Interrupt events are stored in these Raw Interrupt Status registers before masking: RawBlock, RawDstTran, RawErr, RawSrcTran, and RawTfr. Each Raw Interrupt Status register has a bit allocated per channel; for example, RawTfr[2] is the Channel 2 raw transfer complete interrupt.

Each bit in these registers is cleared by writing a 1 to the corresponding location in the ClearTfr, ClearBlock, ClearSrcTran, ClearDstTran, ClearErr registers.

3.31.3 SSP Status Register (SSSR)—Offset 8h

The Enhanced SSP Status registers contain bits that signal overrun errors as well as the Transmit and Receive FIFO service requests. Each of these hardware-detected events signals an Interrupt request to the Interrupt controller. The Status register also contains flags that indicate when the Enhanced SSP is actively transmitting data, when the Transmit FIFO is not full, and when the Receive FIFO is not empty. One Interrupt signal is sent to the Interrupt Controller for each SSP. These events can cause an Interrupt: End-of-Chain, Receiver Time-out, Peripheral Trailing Byte, Receive FIFO overrun, Receive FIFO request, and Transmit FIFO request.

3.31.4 SSP Interrupt Test Register (SSITR)—Offset Ch

The read-write SSP Interrupt Test registers should be used only for testing purposes. Writing a 1 to the test transmit FIFO request SSITR.TTFS, bit 5, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Transmit FIFO. Writing a 1 to the test receive FIFO request SSITR.TRFS, bit 6, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Receive FIFO. Writing a 1 to the test receive FIFO overrun bit SSITR.TROR, bit 7, will generate a non-maskable Interrupt strobe signal to the Interrupt controller only, no DMA request will be made. Setting any of these bits will also cause the corresponding status bit(s) to be set in the Enhanced SSP Status register (SSSR). The Interrupt and/or service request, caused by the setting of one of these test bits, will remain active until the test bit is cleared by writing a 0 it. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

3.31.5 SSP Data (SSDR)—Offset 10h

The Enhanced SSP Data registers are single address locations that Read-Write data transfers can access. The SSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO. As the system accesses the register, FIFO Control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted Write to a full Transmit FIFO). Status bits (such as SSSR.TFL, SSSR.RFL, SSSR.RNE, and SSSR.TNF) show users whether the FIFO is full, above/below a programmable FIFO trigger threshold, or empty. For Transmit data transfers (Write from system to SSP peripheral), the register can be loaded (written) by the system processor anytime it falls below its threshold level when using programmed I/O. When a data size of less than 32-bits is selected, users should not left-justify data written to the Transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data of less than 32-bits is automatically right-justified in the Receive FIFO. When the Enhanced SSP is programmed for National Semiconductor Microwire* frame format and if the size for Transmit data is 8-bits as selected by SSCR1.MWDS=0, then the most significant 24-bits are ignored. Similarly, if the size for the Transmit data is 16-bit as selected by SSCR1.MWDS=1, then most significant 16-bits are ignored. The SSCR0.DSS field controls the Receive data size.

3.31.10 SSP Time Slot Status (SSTSS)—Offset 38h

The Enhanced SSP Time Slot Status registers are read only registers that indicate which Time Slot the Enhanced SSP is currently in when the Enhanced SSP is in Network Mode (SSCR0.MOD = 1). This register is not valid when the Enhanced SSP is not in Network Mode. Note that Writes to reserved bits must be zeroes, and Read values of these bits are undetermined.

3.31.11 SSP Audio Clock Divider (SSACD)—Offset 3Ch

The Enhanced SSP Audio Clock Divider registers are read-write registers that indicate which clock frequency is sent to the Enhanced SSP and to the SYSCLK pin. If SSCR0.SCR is not 0, then there is no guaranteed phase relationship between SYSCLK and SSPSCLK. The SSPSFRM Frame Synch Sampling Frequency is calculated by dividing the chosen PLL output clock frequency (SSACD.ACPS) by the chosen divider (SSACD.ACDS) which gives the SYSCLK frequency. The SYSCLK is then divided by 4 (or by 1) to get the SSPSCLK. The SSPSCLK is divided by the data size (EDSS, DSS values) and by the number of time slots being used (SSCR0.FRDC value), if any, to give the SSPSFRM frequency. Note that Writes to reserved bits must be zeroes, and Read values of these bits are undetermined.

3.33.1 I2C Control Register (IC_CON)—Offset 0h

If configuration parameter I2C_DYNAMIC_TAR_UPDATE = 0, all bits are Read/Write.

If I2C_DYNAMIC_TAR_UPDATE = 1, bit 4 is Read-only.

This register can be written only when the DW_apb_i2c is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

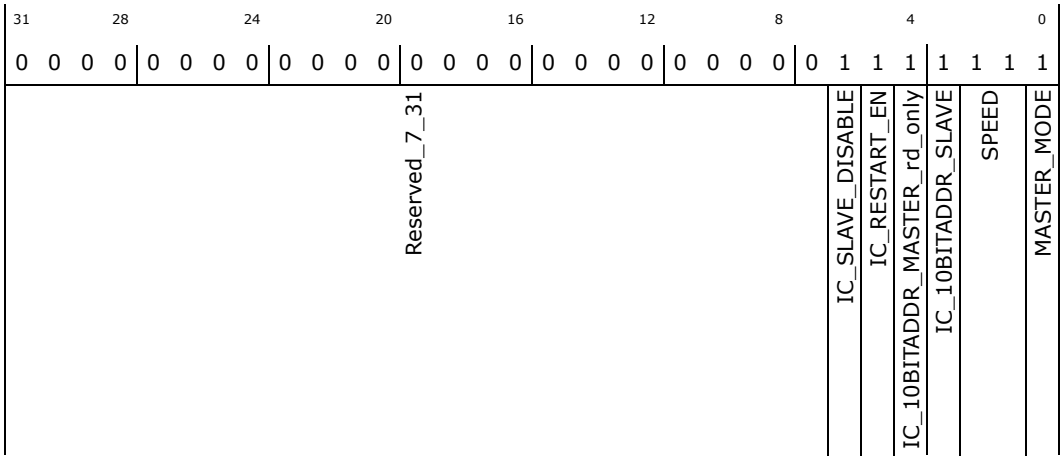
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_CON: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:1] + 10h

Default: 0000007Fh



Bit Range	Default & Access	Description
31:7	0b RW	**Reserved_7_31:** Reserved.
6	1h RW	**IC_SLAVE_DISABLE:** This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	1h RW	**IC_RESTART_EN:** Determines whether RESTART conditions may be sent when acting as a master. When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: • Sending a START BYTE • Performing any high-speed mode operation • Performing direction changes in combined format mode • Performing a read operation with a 10-bit address
4	1h RO	**IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only):** Controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register.
3	1h RW	**IC_10BITADDR_SLAVE:** When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.
2:1	3h RW	**SPEED:** These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	1h RW	**MASTER MODE (MASTER_MODE):** This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

3.33.2 I2C Target Address Register (IC_TAR)—Offset 4h

If the configuration parameter I2C_DYNAMIC_TAR_UPDATE is set to No (0), this register is 12 bits wide, and bits 15:12 are reserved. Writes to this register succeed only when IC_ENABLE is set to 0.

However, if I2C_DYNAMIC_TAR_UPDATE = 1, then the register becomes 13 bits wide. In this case, writes to IC_TAR succeed when one of the following conditions are true:

- DW_apb_i2c is NOT enabled (IC_ENABLE is set to 0)
-
- OR
-
- DW_apb_i2c is enabled (IC_ENABLE=1)
- AND

- DW_apb_i2c is NOT engaged in any Master (tx, rx) operation (IC_STATUS[5]=0)
- AND
- DW_apb_i2c is enabled to operate in Master mode (IC_CON[0]=1)
- AND
- There are NO entries in the TX FIFO (IC_STATUS[2]=1)

Access Method

BAR Type: PCI Configuration Register (Size: 32 bits)

Bit Range	Default & Access	Description
31:13	0b RW	**Reserved_13_31:** Reserved.
12	1h RW	**IC_10BITADDR_MASTER:** This bit controls whether the DW_apb_i2c starts its transfers in 7-or 10-bit addressing mode when acting as a master. This bit exists in this register only if the I2C_DYNAMIC_TAR_UPDATE configuration parameter is set to 1.
11	0h RW	**SPECIAL:** This bit indicates whether software performs a General Call or START BYTE command. • 0 = ignore bit 10 GC_OR_START and use IC_TAR normally • 1 = perform special I2C command as specified in GC_OR_START bit
10	0h RW	**GC_OR_START:** If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.
9:0	55h RW	**IC_TAR:** This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

3.33.3 I2C Slave Address Register (IC_SAR)—Offset 8h

The IC SAR Address Register holds the slave address when the I2C is operating as a slave.

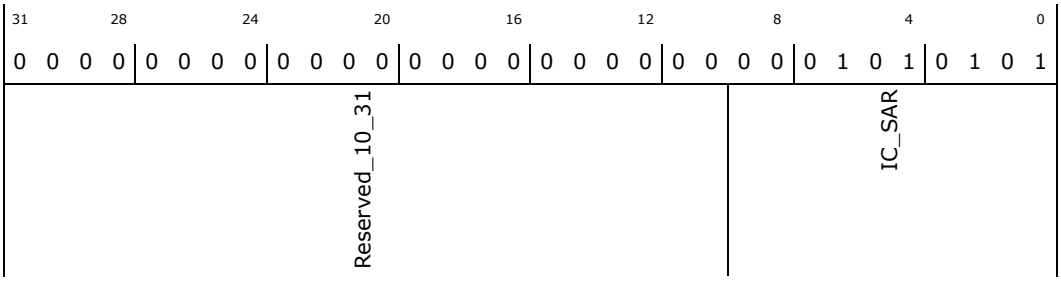
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_SAR: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:1] + 10h

Default: 00000055h



Bit Range	Default & Access	Description
31:10	0b RW	**Reserved_10_31:** Reserved.
9:0	55h RW	**IC_SAR:** The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.33.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

Note: It is not necessary to perform any write to this register if DW_apb_i2c is enabled as an I2C slave only.

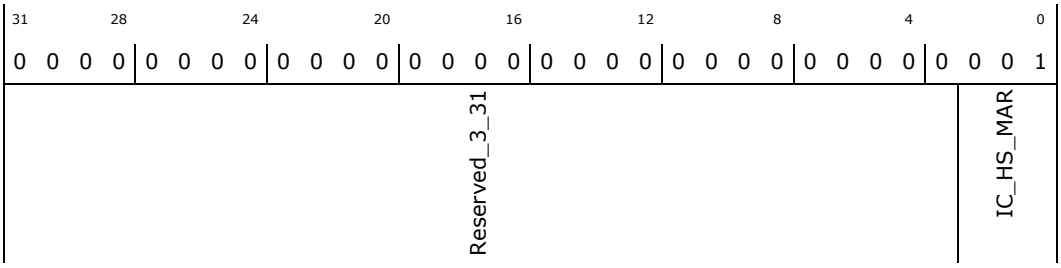
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_HS_MADDR: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:1] + 10h

Default: 00000001h



Bit Range	Default & Access	Description
31:3	0b RW	**Reserved_3_31:** Reserved.
2:0	1h RW	**IC_HS_MAR:** This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register goes away and becomes read-only returning 0s if the IC_MAX_SPEED_MODE configuration parameter is set to either Standard (1) or Fast (2). This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.33.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

This is the register written to by the CPU when filling the TX FIFO, and read from by the CPU when retrieving bytes from RX FIFO.

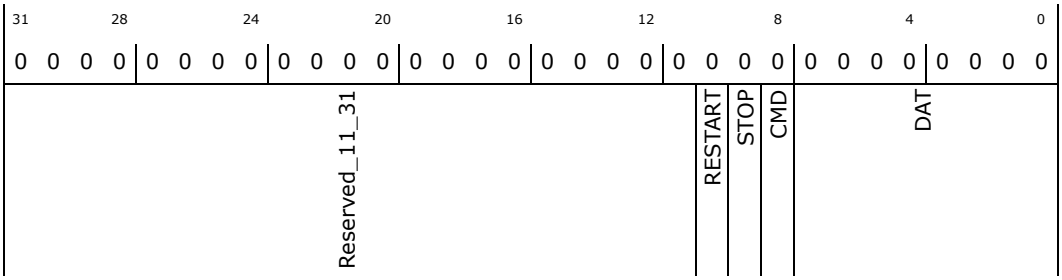
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_DATA_CMD: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:1] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:11	0b RW	**Reserved_11_31:** Reserved.

Bit Range	Default & Access	Description
10	0h RW	**RESTART:** This bit controls whether a RESTART is issued before the byte is sent or received. This bit is available only if IC_EMPTYFIFO_HOLD_MASTER_EN is configured to 1. 1 If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/ received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. 0 If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.
9	0h RW	**STOP:** This bit determines whether STOP is generated after a data byte is sent or received.
8	0h RW	**CMD:** This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It only controls the direction when it acts as a master. • 1 = Read • 0 = Write
7:0	0h RW	**DAT:** This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. When you read this register, however, these bits return the value of data received on the DW_apb_i2c interface.

3.33.10 High Speed I2C Clock SCL High Count Register (IC_HS_SCL_HCNT)—Offset 24h

This register must be set before any I2C bus transaction can take place, to ensure proper I/O timing. This register sets the SCL clock high-period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL. For more information, refer to *IC_CLK Frequency Configuration* .

The SCL High time depends on the loading of the bus. For 100pF loading, the SCL High time is 60ns; for 400pF loading, the SCL High time is 120ns.

This register goes away and becomes read-only if IC_MAX_SPEED_MODE!= high. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

The minimum valid value is 6; hardware prevents values less than this being written, and, if attempted, results in 6 being set. For designs with APB_DATA_WIDTH == 8 the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte can be programmed.

When the configuration parameter IC_HC_COUNT_VALUES is set to 1, this register is read only.

Bit Range	Default & Access	Description
11	0h RO	**R_GEN_CALL:** Set only when a General Call address is received and acknowledged. It stays set until it is cleared either by disabling DW_apb_i2c or when the CPU reads bit 0 of the IC_CLR_GEN_CALL register.

3.33.30 I2C Transmit FIFO Level Register (IC_TXFLR)—Offset 74h

This register contains the number of valid data entries in the transmit FIFO buffer. It is cleared whenever:

- The I2C is disabled
- There is a transmit abort -- that is, TX_ABRT bit is set in the IC_RAW_INTR_STAT register
- The slave bulk transmit mode is aborted

The register increments whenever data is placed into the transmit FIFO and decrements when data is taken from the transmit FIFO.

3.33.31 I2C Receive FIFO Level Register (IC_RXFLR)—Offset 78h

This register contains the number of valid data entries in the receive FIFO buffer. The register is cleared by the following methods:

- The I2C is disabled
- Whenever there is a transmit abort caused by any of the events tracked in IC_TX_ABRT_SOURCE

The register increments whenever data is placed into the receive FIFO and decrements when data is taken from the receive FIFO.

3.33.32 I2C SDA Hold Time Length Register (IC_SDA_HOLD)—Offset 7Ch

This register controls the amount of hold time on the SDA signal after a negative edge of SCL in both master and slave mode, in units of ic_clk period. The value programmed must be greater than the minimum hold time in each mode for the value to be implementedone cycle in master mode, seven cycles in slave mode. Writes to this register succeed only when IC_ENABLE=0.

The programmed SDA hold time cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N_SCL_LOW-2, where N_SCL_LOW is the duration of the low part of the scl period measured in ic_clk cycles.

3.33.33 I2C Transmit Abort Source Register (IC_TX_ABRT_SOURCE)—Offset 80h

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

3.33.34 Generate Slave Data NACK Register (IC_SLV_DATA_NACK_ONLY)—Offset 84h

The register is used to generate a NACK for the data part of a transfer when DW_apb_i2c is acting as a slave-receiver. This register only exists when the IC_SLV_DATA_NACK_ONLY parameter is set to 1. When this parameter disabled, this register does not exist and writing to the registers address has no effect. A write can occur on this register if either of the following conditions are met.

- DW_apb_i2c is disabled (IC_ENABLE[0] = 0)
- Slave part is inactive (IC_STATUS[6] = 0)

NOTE = The IC_STATUS[6] is a register read-back location for the internal slv_activity signal; the user should poll this before writing the ic_slv_data_nack_only bit.

7:0	0h RW	**Receive Data Level (DMARDL):** This bit field controls the level at which a DMA request is made by the receive logic. The watermark level = DMARDL+1; that is, dma_rx_req is generated when the number of valid data entries in the receive FIFO is equal to or more than this field value + 1, and RDMAE =1. For instance, when DMARDL is 0, then dma_rx_req is asserted when 1 or more data entries are present in the receive FIFO.

3.33.38 I2C SDA Setup Register (IC_SDA_SETUP)—Offset 94h

This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL -- relative to SDA changing -- by holding SCL low when DW_apb_i2c services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2.

NOTE: The length of setup time is calculated using [(IC_SDA_SETUP - 1) * (ic_clk_period)], so if the user requires 10 ic_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the DW_apb_i2c when operating as a slave transmitter.

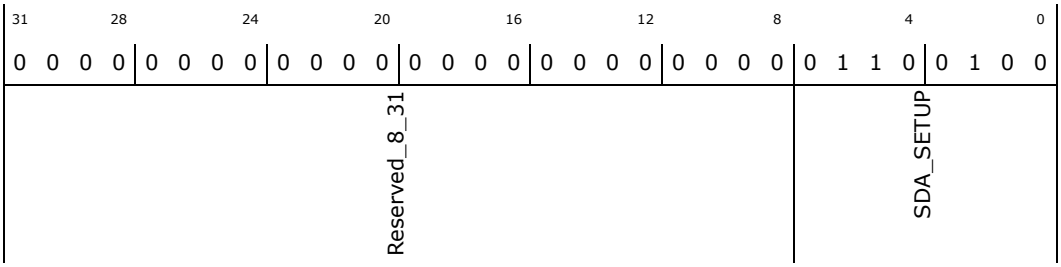
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_SDA_SETUP: [BAR] + 94h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:1] + 10h

Default: 00000064h



Bit Range	Default & Access	Description
31:8	0b RW	**Reserved_8_31:** Reserved.
7:0	64h RW	**SDA Setup (SDA_SETUP):** It is recommended that if the required delay is 1000ns, then for an ic_clk frequency of 10 MHz, IC_SDA_SETUP should be programmed to a value of 11.

3.33.39 I2C ACK General Call Register (IC_ACK_GENERAL_CALL)—Offset 98h

The register controls whether DW_apb_i2c responds with an ACK or NACK when it receives an I2C General Call address.

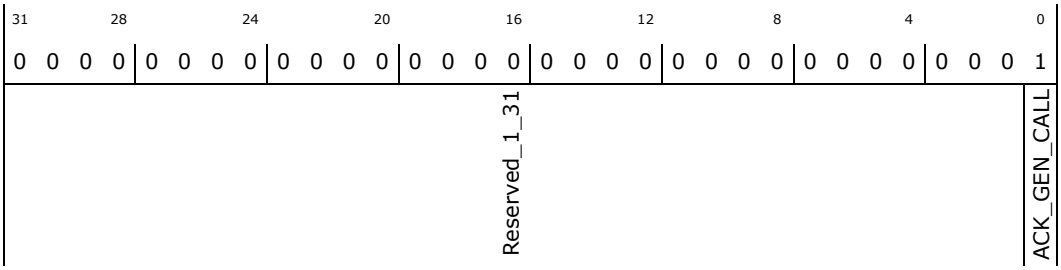
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_ACK_GENERAL_CALL: [BAR] + 98h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:1] + 10h

Default: 00000001h



Bit Range	Default & Access	Description
31:1	0b RW	**Reserved_1_31:** Reserved.
0	1h RW	**ACK General Call (ACK_GEN_CALL):** When set to 1, DW_apb_i2c responds with a ACK (by asserting ic_data_oe) when it receives a General Call. When set to 0, the DW_apb_i2c does not generate General Call interrupts.

3.33.40 I2C Enable Status Register (IC_ENABLE_STATUS)—Offset 9Ch

The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE register is set from 1 to 0, that is, when DW_apb_i2c is disabled.

- If IC_ENABLE has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.
- If IC_ENABLE has been set to 0, bits 2:1 will only be valid as soon as bit 0 is read as 0.

NOTE = When IC_ENABLE has been written with 0, a delay occurs for bit 0 to be read as 0 because disabling the DW_apb_i2c depends on I2C bus activities.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

3.34.11 PowerManagement Capability ID (POWERCAPID)—Offset 80h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

2	0h RO	**Reserved3:** Reserved.
1:0	0h RW	**Power State (POWERSTATE):** This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: • 00 = D0 state • 11 = D3HOT state • Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. 3.35.1 I2C Control Register (IC_CON)—Offset 0h

If configuration parameter I2C_DYNAMIC_TAR_UPDATE = 0, all bits are Read/Write.

If I2C_DYNAMIC_TAR_UPDATE = 1, bit 4 is Read-only.

This register can be written only when the DW_apb_i2c is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

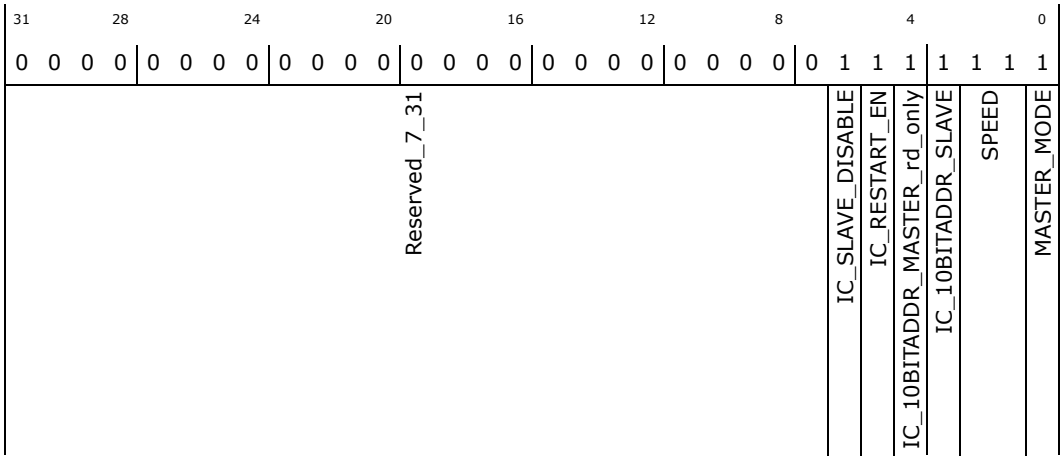
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_CON: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:2] + 10h

Default: 0000007Fh



Bit Range	Default & Access	Description
31:7	0b RW	**Reserved_7_31:** Reserved.
6	1h RW	**IC_SLAVE_DISABLE:** This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	1h RW	**IC_RESTART_EN:** Determines whether RESTART conditions may be sent when acting as a master. When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: • Sending a START BYTE • Performing any high-speed mode operation • Performing direction changes in combined format mode • Performing a read operation with a 10-bit address
4	1h RO	**IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only):** Controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register.
3	1h RW	**IC_10BITADDR_SLAVE:** When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.
2:1	3h RW	**SPEED:** These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	1h RW	**MASTER MODE (MASTER_MODE):** This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

3.35.2 I2C Target Address Register (IC_TAR)—Offset 4h

If the configuration parameter I2C_DYNAMIC_TAR_UPDATE is set to No (0), this register is 12 bits wide, and bits 15:12 are reserved. Writes to this register succeed only when IC_ENABLE is set to 0.

However, if I2C_DYNAMIC_TAR_UPDATE = 1, then the register becomes 13 bits wide. In this case, writes to IC_TAR succeed when one of the following conditions are true:

- DW_apb_i2c is NOT enabled (IC_ENABLE is set to 0)
-
- OR
-
- DW_apb_i2c is enabled (IC_ENABLE=1)
- AND

- DW_apb_i2c is NOT engaged in any Master (tx, rx) operation (IC_STATUS[5]=0)
- AND
- DW_apb_i2c is enabled to operate in Master mode (IC_CON[0]=1)
- AND
- There are NO entries in the TX FIFO (IC_STATUS[2]=1)

Access Method

IC_TAR: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)

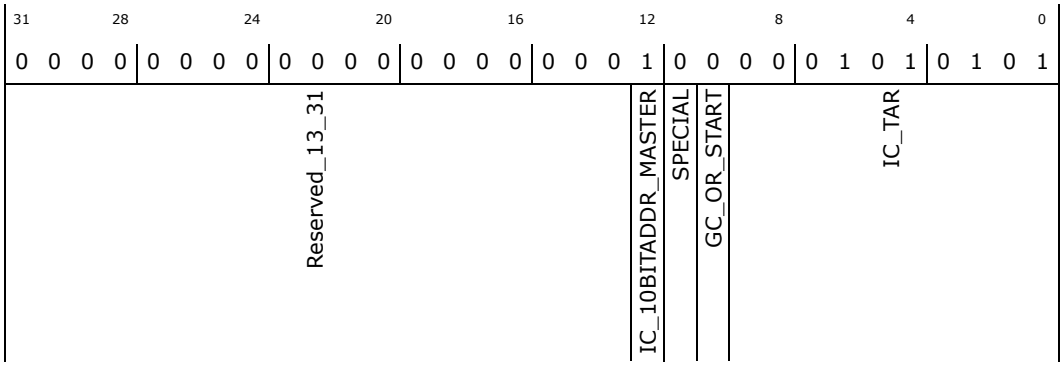
Default: 00001055h



Bit Range	Default & Access	Description
31:13	0b RW	**Reserved_13_31:** Reserved.
12	1h RW	**IC_10BITADDR_MASTER:** This bit controls whether the DW_apb_i2c starts its transfers in 7-or 10-bit addressing mode when acting as a master. This bit exists in this register only if the I2C_DYNAMIC_TAR_UPDATE configuration parameter is set to 1.
11	0h RW	**SPECIAL:** This bit indicates whether software performs a General Call or START BYTE command. • 0 = ignore bit 10 GC_OR_START and use IC_TAR normally • 1 = perform special I2C command as specified in GC_OR_START bit
10	0h RW	**GC_OR_START:** If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.
9:0	55h RW	**IC_TAR:** This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

3.35.3 I2C Slave Address Register (IC_SAR)—Offset 8h

The IC SAR Address Register holds the slave address when the I2C is operating as a slave.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_SAR: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:2] + 10h

Bit Range	Default & Access	Description
31:10	0b RW	**Reserved_10_31:** Reserved.
9:0	55h RW	**IC_SAR:** The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.35.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

Note: It is not necessary to perform any write to this register if DW_apb_i2c is enabled as an I2C slave only.

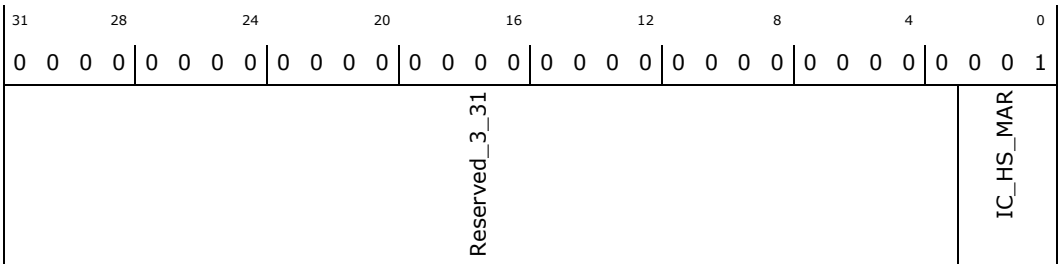
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_HS_MADDR: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:2] + 10h

Default: 00000001h



Bit Range	Default & Access	Description
31:3	0b RW	**Reserved_3_31:** Reserved.
2:0	1h RW	**IC_HS_MAR:** This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highs peed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register goes away and becomes read-only returning 0s if the IC_MAX_SPEED_MODE configuration parameter is set to either Standard (1) or Fast (2). This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.35.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

This is the register written to by the CPU when filling the TX FIFO, and read from by the CPU when retrieving bytes from RX FIFO.

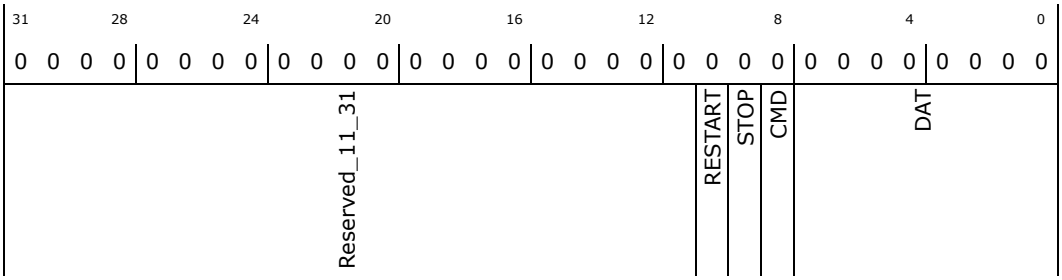
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_DATA_CMD: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:2] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:11	0b RW	**Reserved_11_31:** Reserved.

Bit Range	Default & Access	Description
10	0h RW	**RESTART:** This bit controls whether a RESTART is issued before the byte is sent or received. This bit is available only if IC_EMPTYFIFO_HOLD_MASTER_EN is configured to 1. 1 If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/ received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. 0 If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.
9	0h RW	**STOP:** This bit determines whether STOP is generated after a data byte is sent or received.
8	0h RW	**CMD:** This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It only controls the direction when it acts as a master. • 1 = Read • 0 = Write
7:0	0h RW	**DAT:** This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. When you read this register, however, these bits return the value of data received on the DW_apb_i2c interface.

3.35.10 High Speed I2C Clock SCL High Count Register (IC_HS_SCL_HCNT)—Offset 24h

This register must be set before any I2C bus transaction can take place, to ensure proper I/O timing. This register sets the SCL clock high-period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL. For more information, refer to *IC_CLK Frequency Configuration* .

The SCL High time depends on the loading of the bus. For 100pF loading, the SCL High time is 60ns; for 400pF loading, the SCL High time is 120ns.

This register goes away and becomes read-only if IC_MAX_SPEED_MODE!= high. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

The minimum valid value is 6; hardware prevents values less than this being written, and, if attempted, results in 6 being set. For designs with APB_DATA_WIDTH == 8 the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte can be programmed.

When the configuration parameter IC_HC_COUNT_VALUES is set to 1, this register is read only.

3.35.11 High Speed I2C Clock SCL Low Count Register (IC_HS_SCL_LCNT)—Offset 28h

This register must be set before any I2C bus transaction can take place, to ensure proper I/O timing. This register sets the SCL clock low-period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL. For more information, refer to *IC_CLK Frequency Configuration* in the Synopsis DesignWare DW_apb_i2c Databook.

The SCL High time depends on the loading of the bus. For 100pF loading, the SCL High time is 60ns; for 400pF loading, the SCL High time is 120ns.

This register goes away and becomes read-only if IC_MAX_SPEED_MODE!= high. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

The minimum valid value is 8; hardware prevents values less than this being written, and, if attempted, results in 8 being set. For designs with APB_DATA_WIDTH == 8 the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte can be programmed.

When the configuration parameter IC_HC_COUNT_VALUES is set to 1, this register is read only.

3.35.32 I2C SDA Hold Time Length Register (IC_SDA_HOLD)—Offset 7Ch

This register controls the amount of hold time on the SDA signal after a negative edge of SCL in both master and slave mode, in units of ic_clk period. The value programmed must be greater than the minimum hold time in each mode for the value to be implemented one cycle in master mode, seven cycles in slave mode. Writes to this register succeed only when IC_ENABLE=0.

The programmed SDA hold time cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N_SCL_LOW-2, where N_SCL_LOW is the duration of the low part of the scl period measured in ic_clk cycles.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

3.35.33 I2C Transmit Abort Source Register (IC_TX_ABRT_SOURCE)—Offset 80h

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

3.35.34 Generate Slave Data NACK Register (IC_SLV_DATA_NACK_ONLY)—Offset 84h

The register is used to generate a NACK for the data part of a transfer when DW_apb_i2c is acting as a slave-receiver. This register only exists when the IC_SLV_DATA_NACK_ONLY parameter is set to 1. When this parameter disabled, this register does not exist and writing to the registers address has no effect. A write can occur on this register if either of the following conditions are met.

- DW_apb_i2c is disabled (IC_ENABLE[0] = 0)
- Slave part is inactive (IC_STATUS[6] = 0)

NOTE = The IC_STATUS[6] is a register read-back location for the internal slv_activity signal; the user should poll this before writing the ic_slv_data_nack_only bit.

Access Method

IC_SLV_DATA_NACK_ONLY: [BAR] + 84h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:2] + 10h

31:1	0b RW	**Reserved_1_31:** Reserved.
0	0h RW	**Generate NACK (NACK):** This NACK generation only occurs when DW_apb_i2c is a slave receiver. If this register is set to a value of 1, it can only generate a NACK after a data byte is received; hence, the data transfer is aborted and the data received is not pushed to the receive buffer. When the register is set to a value of 0, it generates NACK/ACK, depending on normal criteria. • 1 = generate NACK after data byte received • 0 = generate NACK/ACK normally

3.35.35 DMA Control Register (IC_DMA_CR)—Offset 88h

This register is only valid when DW_apb_i2c is configured with a set of DMA Controller interface signals (IC_HAS_DMA = 1). When DW_apb_i2c is not configured for DMA operation, this register does not exist and writing to the registers address has no effect and reading from this register address will return zero. The register is used to enable the DMA Controller interface operation. There is a separate bit for transmit and receive. This can be programmed regardless of the state of IC_ENABLE.

3.35.36 DMA Transmit Data Level Register (IC_DMA_TDLR)—Offset 8Ch

This register is only valid when the DW_apb_i2c is configured with a set of DMA interface signals (IC_HAS_DMA = 1). When DW_apb_i2c is not configured for DMA operation, this register does not exist, writing to its address has no effect, and reading from its address returns zero.

3.35.37 I2C Receive Data Level Register (IC_DMA_RDLR)—Offset 90h

This register is only valid when DW_apb_i2c is configured with a set of DMA interface signals(IC_HAS_DMA = 1). When DW_apb_i2c is not configured for DMA operation, this register does not exist, writing to its address has no effect, and reading from its address returns zero.

7:0	0h RW	**Receive Data Level (DMARDL):** This bit field controls the level at which a DMA request is made by the receive logic. The watermark level = DMARDL+1; that is, dma_rx_req is generated when the number of valid data entries in the receive FIFO is equal to or more than this field value + 1, and RDMAE =1. For instance, when DMARDL is 0, then dma_rx_req is asserted when 1 or more data entries are present in the receive FIFO.

3.35.38 I2C SDA Setup Register (IC_SDA_SETUP)—Offset 94h

This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL -- relative to SDA changing -- by holding SCL low when DW_apb_i2c services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2.

NOTE: The length of setup time is calculated using [(IC_SDA_SETUP - 1) * (ic_clk_period)], so if the user requires 10 ic_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the DW_apb_i2c when operating as a slave transmitter.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_SDA_SETUP: [BAR] + 94h

BAR Type: PCI Configuration Register (Size: 32 bits)

3.35.39 I2C ACK General Call Register (IC_ACK_GENERAL_CALL)—Offset 98h

31:1	0b RW	**Reserved_1_31:** Reserved.
0	1h RW	**ACK General Call (ACK_GEN_CALL):** When set to 1, DW_apb_i2c responds with a ACK (by asserting ic_data_oe) when it receives a General Call. When set to 0, the DW_apb_i2c does not generate General Call interrupts.

3.35.40 I2C Enable Status Register (IC_ENABLE_STATUS)—Offset 9Ch

The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE register is set from 1 to 0, that is, when DW_apb_i2c is disabled.

- If IC_ENABLE has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.
- If IC_ENABLE has been set to 0, bits 2:1 will only be valid as soon as bit 0 is read as 0.

NOTE = When IC_ENABLE has been written with 0, a delay occurs for bit 0 to be read as 0 because disabling the DW_apb_i2c depends on I2C bus activities.

The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	**Revision ID (RID):** Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

3.37.1 I2C Control Register (IC_CON)—Offset 0h

If configuration parameter I2C_DYNAMIC_TAR_UPDATE = 0, all bits are Read/Write.

If I2C_DYNAMIC_TAR_UPDATE = 1, bit 4 is Read-only.

This register can be written only when the DW_apb_i2c is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

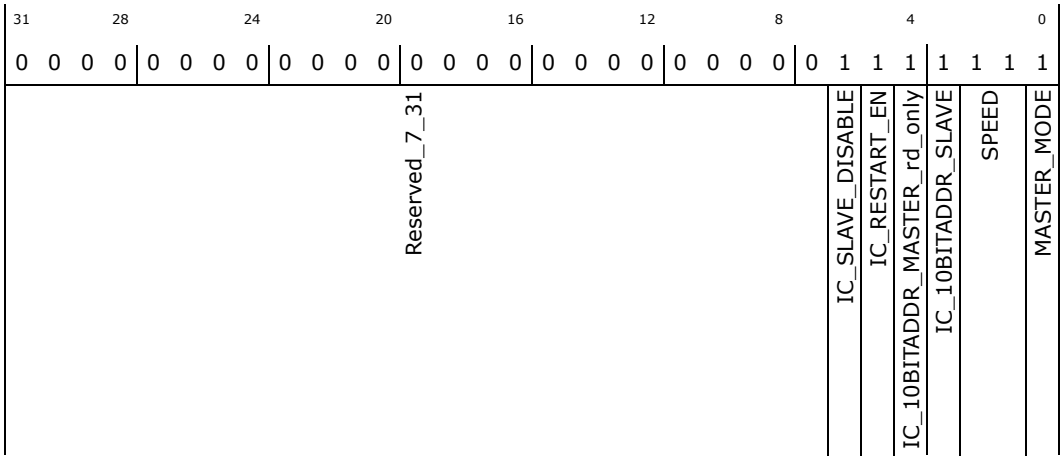
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_CON: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:3] + 10h

Default: 0000007Fh



Bit Range	Default & Access	Description
31:7	0b RW	**Reserved_7_31:** Reserved.
6	1h RW	**IC_SLAVE_DISABLE:** This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	1h RW	**IC_RESTART_EN:** Determines whether RESTART conditions may be sent when acting as a master. When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: • Sending a START BYTE • Performing any high-speed mode operation • Performing direction changes in combined format mode • Performing a read operation with a 10-bit address
4	1h RO	**IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only):** Controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register.
3	1h RW	**IC_10BITADDR_SLAVE:** When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.
2:1	3h RW	**SPEED:** These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	1h RW	**MASTER MODE (MASTER_MODE):** This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

3.37.2 I2C Target Address Register (IC_TAR)—Offset 4h

If the configuration parameter I2C_DYNAMIC_TAR_UPDATE is set to No (0), this register is 12 bits wide, and bits 15:12 are reserved. Writes to this register succeed only when IC_ENABLE is set to 0.

However, if I2C_DYNAMIC_TAR_UPDATE = 1, then the register becomes 13 bits wide. In this case, writes to IC_TAR succeed when one of the following conditions are true:

- DW_apb_i2c is NOT enabled (IC_ENABLE is set to 0)
-
- OR
-
- DW_apb_i2c is enabled (IC_ENABLE=1)
- AND

- DW_apb_i2c is NOT engaged in any Master (tx, rx) operation (IC_STATUS[5]=0)
- AND
- DW_apb_i2c is enabled to operate in Master mode (IC_CON[0]=1)
- AND
- There are NO entries in the TX FIFO (IC_STATUS[2]=1)

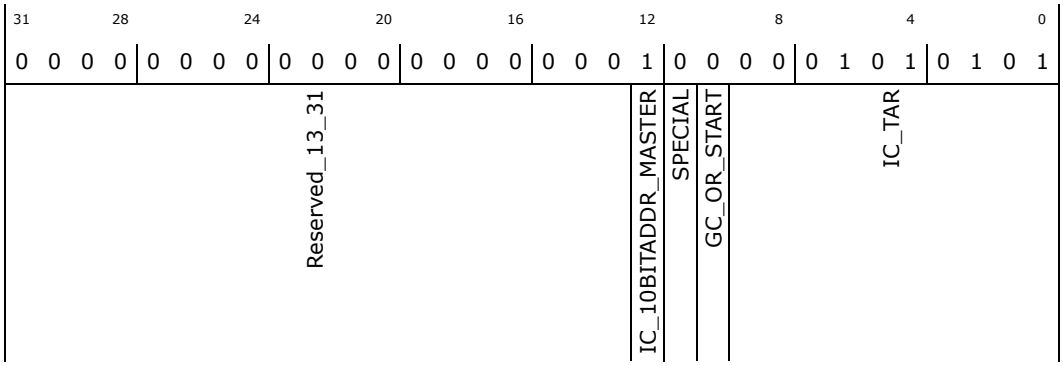
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_TAR: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:3] + 10h

Default: 00001055h



Bit Range	Default & Access	Description
31:13	0b RW	**Reserved_13_31:** Reserved.
12	1h RW	**IC_10BITADDR_MASTER:** This bit controls whether the DW_apb_i2c starts its transfers in 7-or 10-bit addressing mode when acting as a master. This bit exists in this register only if the I2C_DYNAMIC_TAR_UPDATE configuration parameter is set to 1.
11	0h RW	**SPECIAL:** This bit indicates whether software performs a General Call or START BYTE command. • 0 = ignore bit 10 GC_OR_START and use IC_TAR normally • 1 = perform special I2C command as specified in GC_OR_START bit
10	0h RW	**GC_OR_START:** If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.
9:0	55h RW	**IC_TAR:** This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

3.37.3 I2C Slave Address Register (IC_SAR)—Offset 8h

The IC SAR Address Register holds the slave address when the I2C is operating as a slave.

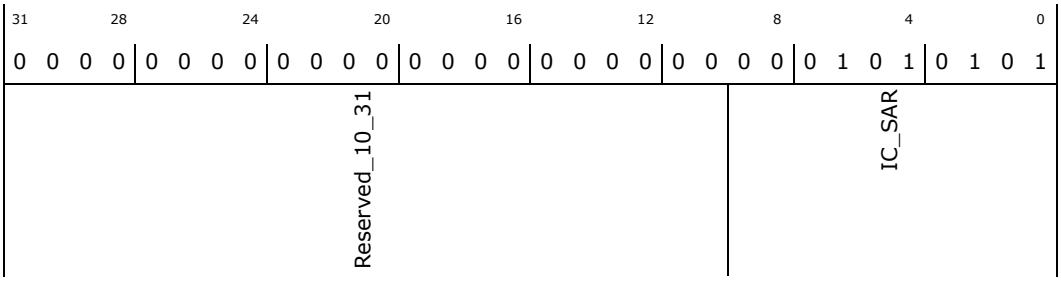
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_SAR: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:3] + 10h

Default: 00000055h



Bit Range	Default & Access	Description
31:10	0b RW	**Reserved_10_31:** Reserved.
9:0	55h RW	**IC_SAR:** The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.37.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

Note: It is not necessary to perform any write to this register if DW_apb_i2c is enabled as an I2C slave only.

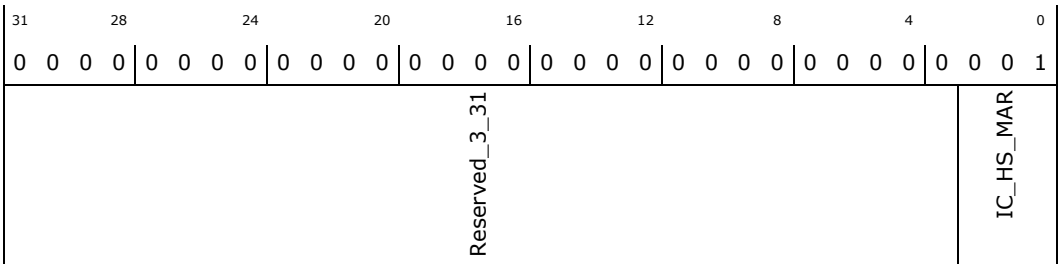
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_HS_MADDR: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:3] + 10h

Default: 00000001h



Bit Range	Default & Access	Description
31:3	0b RW	**Reserved_3_31:** Reserved.
2:0	1h RW	**IC_HS_MAR:** This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highs peed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register goes away and becomes read-only returning 0s if the IC_MAX_SPEED_MODE configuration parameter is set to either Standard (1) or Fast (2). This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.37.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

This is the register written to by the CPU when filling the TX FIFO, and read from by the CPU when retrieving bytes from RX FIFO.

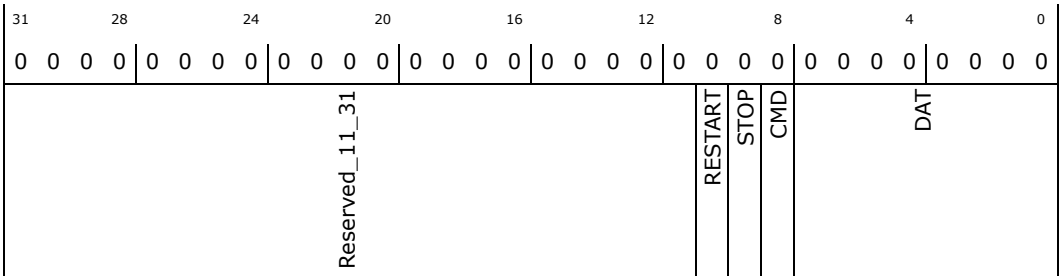
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_DATA_CMD: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:3] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:11	0b RW	**Reserved_11_31:** Reserved.

Bit Range	Default & Access	Description
10	0h RW	**RESTART:** This bit controls whether a RESTART is issued before the byte is sent or received. This bit is available only if IC_EMPTYFIFO_HOLD_MASTER_EN is configured to 1. 1 If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/ received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. 0 If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.
9	0h RW	**STOP:** This bit determines whether STOP is generated after a data byte is sent or received.
8	0h RW	**CMD:** This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It only controls the direction when it acts as a master. • 1 = Read • 0 = Write
7:0	0h RW	**DAT:** This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. When you read this register, however, these bits return the value of data received on the DW_apb_i2c interface.

3.37.6 Standard Speed I2C Clock SCL High Count Register (IC_SS_SCL_HCNT)—Offset 14h

3.37.10 High Speed I2C Clock SCL High Count Register (IC_HS_SCL_HCNT)—Offset 24h

This register must be set before any I2C bus transaction can take place, to ensure proper I/O timing. This register sets the SCL clock high-period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL. For more information, refer to *IC_CLK Frequency Configuration* .

The SCL High time depends on the loading of the bus. For 100pF loading, the SCL High time is 60ns; for 400pF loading, the SCL High time is 120ns.

This register goes away and becomes read-only if IC_MAX_SPEED_MODE!= high. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

The minimum valid value is 6; hardware prevents values less than this being written, and, if attempted, results in 6 being set. For designs with APB_DATA_WIDTH == 8 the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte can be programmed.

When the configuration parameter IC_HC_COUNT_VALUES is set to 1, this register is read only.

3.37.31 I2C Receive FIFO Level Register (IC_RXFLR)—Offset 78h

This register contains the number of valid data entries in the receive FIFO buffer. The register is cleared by the following methods:

- The I2C is disabled
- Whenever there is a transmit abort caused by any of the events tracked in IC_TX_ABRT_SOURCE

The register increments whenever data is placed into the receive FIFO and decrements when data is taken from the receive FIFO.

3.37.32 I2C SDA Hold Time Length Register (IC_SDA_HOLD)—Offset 7Ch

This register controls the amount of hold time on the SDA signal after a negative edge of SCL in both master and slave mode, in units of ic_clk period. The value programmed must be greater than the minimum hold time in each mode for the value to be implemented one cycle in master mode, seven cycles in slave mode. Writes to this register succeed only when IC_ENABLE=0.

The programmed SDA hold time cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N_SCL_LOW-2, where N_SCL_LOW is the duration of the low part of the scl period measured in ic_clk cycles.

3.37.33 I2C Transmit Abort Source Register (IC_TX_ABRT_SOURCE)—Offset 80h

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

3.37.34 Generate Slave Data NACK Register (IC_SLV_DATA_NACK_ONLY)—Offset 84h

The register is used to generate a NACK for the data part of a transfer when DW_apb_i2c is acting as a slave-receiver. This register only exists when the IC_SLV_DATA_NACK_ONLY parameter is set to 1. When this parameter disabled, this register does not exist and writing to the registers address has no effect. A write can occur on this register if either of the following conditions are met.

- DW_apb_i2c is disabled (IC_ENABLE[0] = 0)
- Slave part is inactive (IC_STATUS[6] = 0)

NOTE = The IC_STATUS[6] is a register read-back location for the internal slv_activity signal; the user should poll this before writing the ic_slv_data_nack_only bit.

3.37.35 DMA Control Register (IC_DMA_CR)—Offset 88h

This register is only valid when DW_apb_i2c is configured with a set of DMA Controller interface signals (IC_HAS_DMA = 1). When DW_apb_i2c is not configured for DMA operation, this register does not exist and writing to the registers address has no effect and reading from this register address will return zero. The register is used to enable the DMA Controller interface operation. There is a separate bit for transmit and receive. This can be programmed regardless of the state of IC_ENABLE.

For instance, when DMARDL is 0, then dma_rx_req is asserted when 1 or more data entries are present in the receive FIFO.

3.37.38 I2C SDA Setup Register (IC_SDA_SETUP)—Offset 94h

This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL -- relative to SDA changing -- by holding SCL low when DW_apb_i2c services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2.

NOTE: The length of setup time is calculated using [(IC_SDA_SETUP - 1) * (ic_clk_period)], so if the user requires 10 ic_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the DW_apb_i2c when operating as a slave transmitter.

3.37.40 I2C Enable Status Register (IC_ENABLE_STATUS)—Offset 9Ch

The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE register is set from 1 to 0, that is, when DW_apb_i2c is disabled.

- If IC_ENABLE has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.
- If IC_ENABLE has been set to 0, bits 2:1 will only be valid as soon as bit 0 is read as 0.

NOTE = When IC_ENABLE has been written with 0, a delay occurs for bit 0 to be read as 0 because disabling the DW_apb_i2c depends on I2C bus activities.

30	0h RW/1C	**SSE:** Reserved.
29	0h RW/1C	**Received Master Abort (RMA):** If the completion status received from IOSF is UR, Bridge sets this bit. S/W writes a 1. to this bit to clear it. This bit will not be set for the Fabric port. This bit is not used for the Fabric Port.
28	0h RW/1C	**Received Target Abort (RTA):** If the completion status received from IOSF is CA, Bridge sets this bit. S/W writes a 1.1 to this bit to clear it. This bit will not be set for the fabric port. This bit is not used for the Fabric Port.

3.39.1 I2C Control Register (IC_CON)—Offset 0h

If configuration parameter I2C_DYNAMIC_TAR_UPDATE = 0, all bits are Read/Write.

If I2C_DYNAMIC_TAR_UPDATE = 1, bit 4 is Read-only.

This register can be written only when the DW_apb_i2c is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

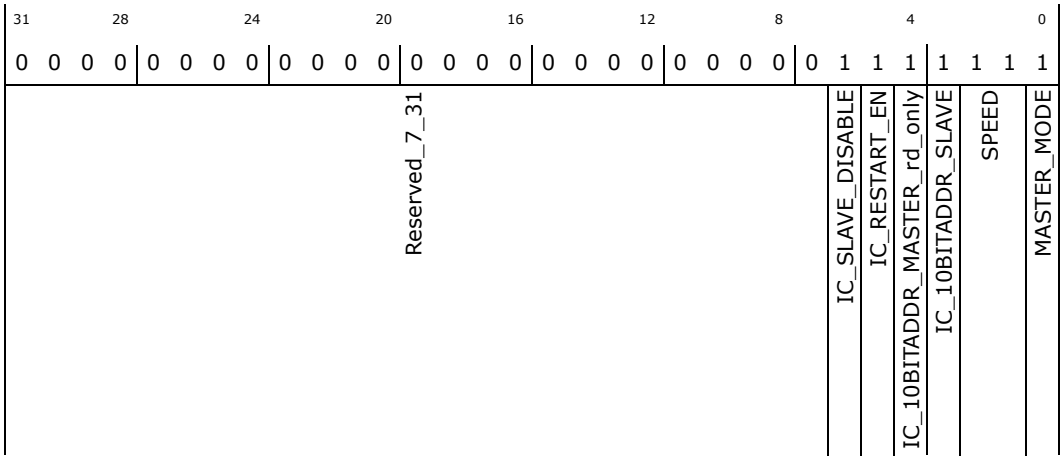
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_CON: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:4] + 10h

Default: 0000007Fh



Bit Range	Default & Access	Description
31:7	0b RW	**Reserved_7_31:** Reserved.
6	1h RW	**IC_SLAVE_DISABLE:** This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	1h RW	**IC_RESTART_EN:** Determines whether RESTART conditions may be sent when acting as a master. When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: • Sending a START BYTE • Performing any high-speed mode operation • Performing direction changes in combined format mode • Performing a read operation with a 10-bit address
4	1h RO	**IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only):** Controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register.
3	1h RW	**IC_10BITADDR_SLAVE:** When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.
2:1	3h RW	**SPEED:** These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	1h RW	**MASTER MODE (MASTER_MODE):** This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

3.39.2 I2C Target Address Register (IC_TAR)—Offset 4h

If the configuration parameter I2C_DYNAMIC_TAR_UPDATE is set to No (0), this register is 12 bits wide, and bits 15:12 are reserved. Writes to this register succeed only when IC_ENABLE is set to 0.

However, if I2C_DYNAMIC_TAR_UPDATE = 1, then the register becomes 13 bits wide. In this case, writes to IC_TAR succeed when one of the following conditions are true:

- DW_apb_i2c is NOT enabled (IC_ENABLE is set to 0)
-
- OR
-
- DW_apb_i2c is enabled (IC_ENABLE=1)
- AND

- DW_apb_i2c is NOT engaged in any Master (tx, rx) operation (IC_STATUS[5]=0)
- AND
- DW_apb_i2c is enabled to operate in Master mode (IC_CON[0]=1)
- AND
- There are NO entries in the TX FIFO (IC_STATUS[2]=1)

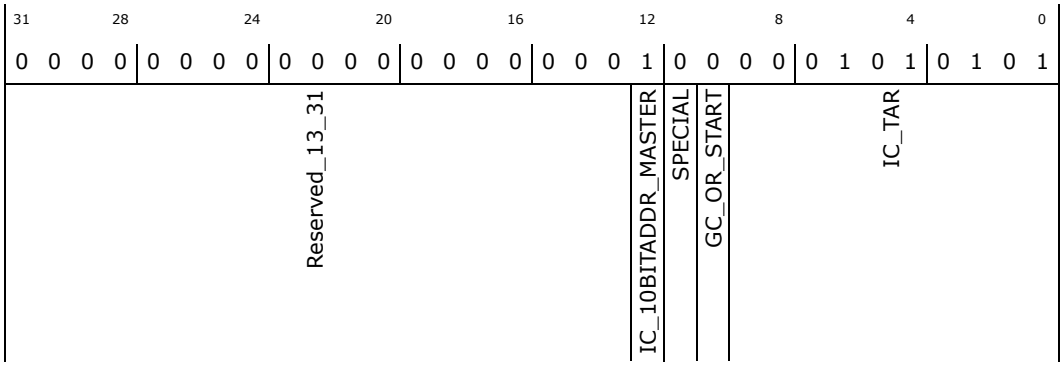
BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:4] + 10h

Default: 00001055h



Bit Range	Default & Access	Description
31:13	0b RW	**Reserved_13_31:** Reserved.
12	1h RW	**IC_10BITADDR_MASTER:** This bit controls whether the DW_apb_i2c starts its transfers in 7-or 10-bit addressing mode when acting as a master. This bit exists in this register only if the I2C_DYNAMIC_TAR_UPDATE configuration parameter is set to 1.
11	0h RW	**SPECIAL:** This bit indicates whether software performs a General Call or START BYTE command. • 0 = ignore bit 10 GC_OR_START and use IC_TAR normally • 1 = perform special I2C command as specified in GC_OR_START bit
10	0h RW	**GC_OR_START:** If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.
9:0	55h RW	**IC_TAR:** This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

3.39.3 I2C Slave Address Register (IC_SAR)—Offset 8h

The IC SAR Address Register holds the slave address when the I2C is operating as a slave.

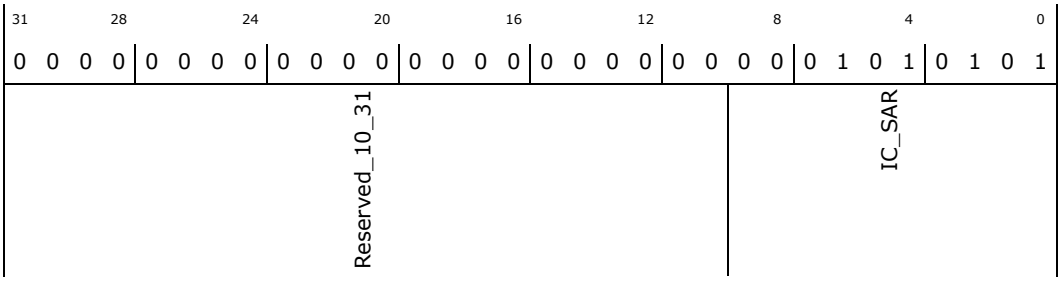
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_SAR: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:4] + 10h

Default: 00000055h



Bit Range	Default & Access	Description
31:10	0b RW	**Reserved_10_31:** Reserved.
9:0	55h RW	**IC_SAR:** The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.39.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

Note: It is not necessary to perform any write to this register if DW_apb_i2c is enabled as an I2C slave only.

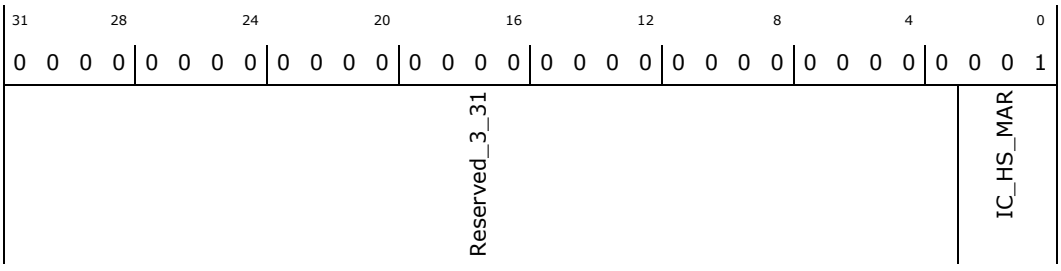
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_HS_MADDR: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:4] + 10h

Default: 00000001h



Bit Range	Default & Access	Description
31:3	0b RW	**Reserved_3_31:** Reserved.
2:0	1h RW	**IC_HS_MAR:** This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highs peed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register goes away and becomes read-only returning 0s if the IC_MAX_SPEED_MODE configuration parameter is set to either Standard (1) or Fast (2). This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.39.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

This is the register written to by the CPU when filling the TX FIFO, and read from by the CPU when retrieving bytes from RX FIFO.

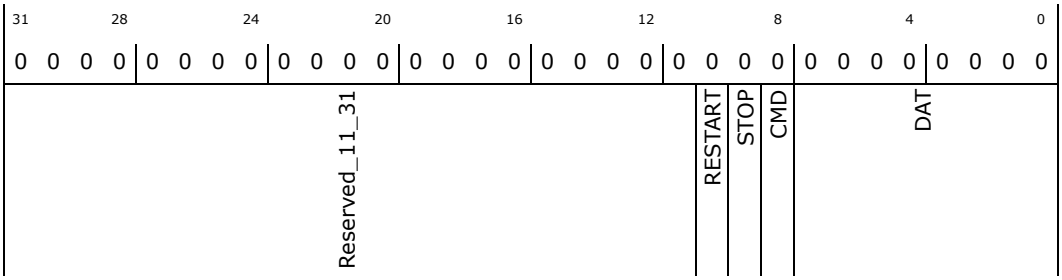
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_DATA_CMD: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:4] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:11	0b RW	**Reserved_11_31:** Reserved.

Bit Range	Default & Access	Description
10	0h RW	**RESTART:** This bit controls whether a RESTART is issued before the byte is sent or received. This bit is available only if IC_EMPTYFIFO_HOLD_MASTER_EN is configured to 1. 1 If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/ received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. 0 If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.
9	0h RW	**STOP:** This bit determines whether STOP is generated after a data byte is sent or received.
8	0h RW	**CMD:** This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It only controls the direction when it acts as a master. • 1 = Read • 0 = Write
7:0	0h RW	**DAT:** This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. When you read this register, however, these bits return the value of data received on the DW_apb_i2c interface.

3.39.10 High Speed I2C Clock SCL High Count Register (IC_HS_SCL_HCNT)—Offset 24h

This register must be set before any I2C bus transaction can take place, to ensure proper I/O timing. This register sets the SCL clock high-period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL. For more information, refer to *IC_CLK Frequency Configuration* .

The SCL High time depends on the loading of the bus. For 100pF loading, the SCL High time is 60ns; for 400pF loading, the SCL High time is 120ns.

This register goes away and becomes read-only if IC_MAX_SPEED_MODE!= high. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

The minimum valid value is 6; hardware prevents values less than this being written, and, if attempted, results in 6 being set. For designs with APB_DATA_WIDTH == 8 the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte can be programmed.

When the configuration parameter IC_HC_COUNT_VALUES is set to 1, this register is read only.

3.39.30 I2C Transmit FIFO Level Register (IC_TXFLR)—Offset 74h

This register contains the number of valid data entries in the transmit FIFO buffer. It is cleared whenever:

- The I2C is disabled
- There is a transmit abort -- that is, TX_ABRT bit is set in the IC_RAW_INTR_STAT register
- The slave bulk transmit mode is aborted

The register increments whenever data is placed into the transmit FIFO and decrements when data is taken from the transmit FIFO.

- The I2C is disabled
- Whenever there is a transmit abort caused by any of the events tracked in IC_TX_ABRT_SOURCE

The register increments whenever data is placed into the receive FIFO and decrements when data is taken from the receive FIFO.

3.39.32 I2C SDA Hold Time Length Register (IC_SDA_HOLD)—Offset 7Ch

This register controls the amount of hold time on the SDA signal after a negative edge of SCL in both master and slave mode, in units of ic_clk period. The value programmed must be greater than the minimum hold time in each mode for the value to be implemented one cycle in master mode, seven cycles in slave mode. Writes to this register succeed only when IC_ENABLE=0.

The programmed SDA hold time cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N_SCL_LOW-2, where N_SCL_LOW is the duration of the low part of the scl period measured in ic_clk cycles.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

3.39.33 I2C Transmit Abort Source Register (IC_TX_ABRT_SOURCE)—Offset 80h

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

3.39.34 Generate Slave Data NACK Register (IC_SLV_DATA_NACK_ONLY)—Offset 84h

The register is used to generate a NACK for the data part of a transfer when DW_apb_i2c is acting as a slave-receiver. This register only exists when the IC_SLV_DATA_NACK_ONLY parameter is set to 1. When this parameter disabled, this register does not exist and writing to the registers address has no effect. A write can occur on this register if either of the following conditions are met.

- DW_apb_i2c is disabled (IC_ENABLE[0] = 0)
- Slave part is inactive (IC_STATUS[6] = 0)

NOTE = The IC_STATUS[6] is a register read-back location for the internal slv_activity signal; the user should poll this before writing the ic_slv_data_nack_only bit.

When the register is set to a value of 0, it generates NACK/ACK, depending on normal criteria. • 1 = generate NACK after data byte received • 0 = generate NACK/ACK normally

3.39.35 DMA Control Register (IC_DMA_CR)—Offset 88h

This register is only valid when DW_apb_i2c is configured with a set of DMA Controller interface signals (IC_HAS_DMA = 1). When DW_apb_i2c is not configured for DMA operation, this register does not exist and writing to the registers address has no effect and reading from this register address will return zero. The register is used to enable the DMA Controller interface operation. There is a separate bit for transmit and receive. This can be programmed regardless of the state of IC_ENABLE.

For instance, when DMARDL is 0, then dma_rx_req is asserted when 1 or more data entries are present in the receive FIFO.

3.39.38 I2C SDA Setup Register (IC_SDA_SETUP)—Offset 94h

This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL -- relative to SDA changing -- by holding SCL low when DW_apb_i2c services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2.

NOTE: The length of setup time is calculated using [(IC_SDA_SETUP - 1) * (ic_clk_period)], so if the user requires 10 ic_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the DW_apb_i2c when operating as a slave transmitter.

3.39.40 I2C Enable Status Register (IC_ENABLE_STATUS)—Offset 9Ch

The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE register is set from 1 to 0, that is, when DW_apb_i2c is disabled.

3.41.1 I2C Control Register (IC_CON)—Offset 0h

If configuration parameter I2C_DYNAMIC_TAR_UPDATE = 0, all bits are Read/Write.

If I2C_DYNAMIC_TAR_UPDATE = 1, bit 4 is Read-only.

This register can be written only when the DW_apb_i2c is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

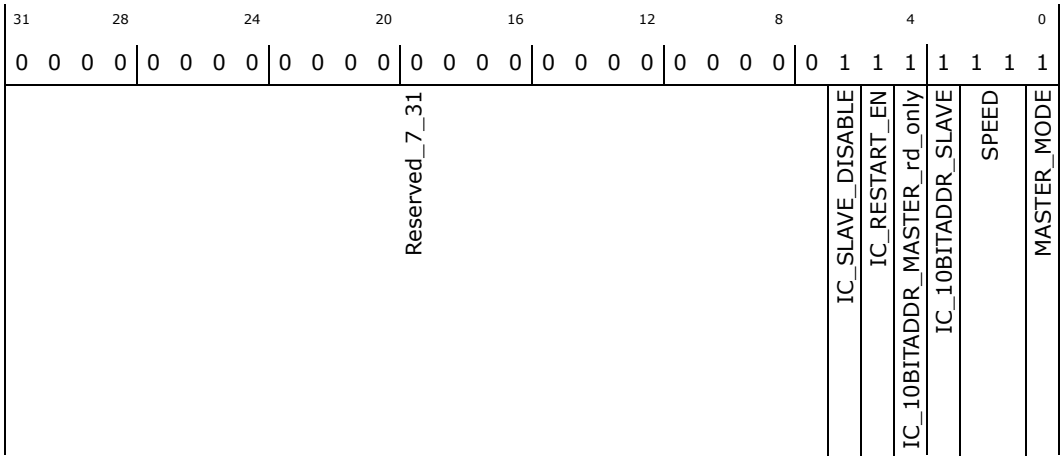
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_CON: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:5] + 10h

Default: 0000007Fh



Bit Range	Default & Access	Description
31:7	0b RW	**Reserved_7_31:** Reserved.
6	1h RW	**IC_SLAVE_DISABLE:** This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	1h RW	**IC_RESTART_EN:** Determines whether RESTART conditions may be sent when acting as a master. When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: • Sending a START BYTE • Performing any high-speed mode operation • Performing direction changes in combined format mode • Performing a read operation with a 10-bit address
4	1h RO	**IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only):** Controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register.
3	1h RW	**IC_10BITADDR_SLAVE:** When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.
2:1	3h RW	**SPEED:** These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	1h RW	**MASTER MODE (MASTER_MODE):** This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

3.41.2 I2C Target Address Register (IC_TAR)—Offset 4h

If the configuration parameter I2C_DYNAMIC_TAR_UPDATE is set to No (0), this register is 12 bits wide, and bits 15:12 are reserved. Writes to this register succeed only when IC_ENABLE is set to 0.

However, if I2C_DYNAMIC_TAR_UPDATE = 1, then the register becomes 13 bits wide. In this case, writes to IC_TAR succeed when one of the following conditions are true:

- DW_apb_i2c is NOT enabled (IC_ENABLE is set to 0)
-
- OR
-
- DW_apb_i2c is enabled (IC_ENABLE=1)
- AND

- DW_apb_i2c is NOT engaged in any Master (tx, rx) operation (IC_STATUS[5]=0)
- AND
- DW_apb_i2c is enabled to operate in Master mode (IC_CON[0]=1)
- AND
- There are NO entries in the TX FIFO (IC_STATUS[2]=1)

Access Method

BAR Type: PCI Configuration Register (Size: 32 bits)

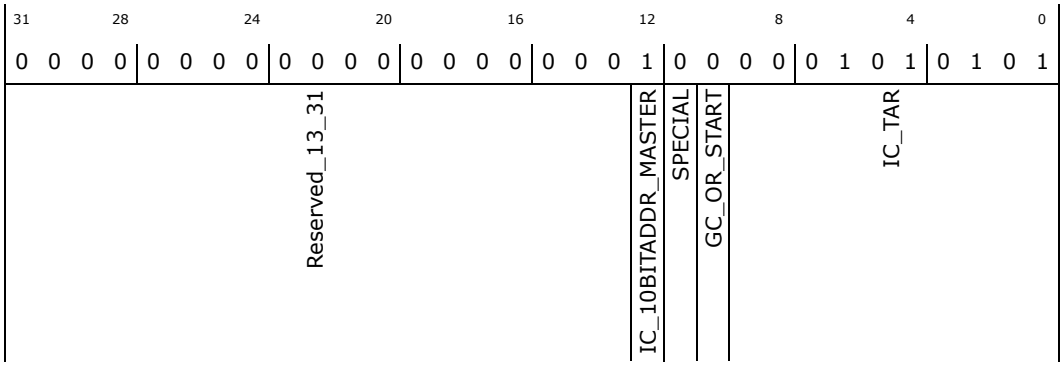
Default: 00001055h



Bit Range	Default & Access	Description
31:13	0b RW	**Reserved_13_31:** Reserved.
12	1h RW	**IC_10BITADDR_MASTER:** This bit controls whether the DW_apb_i2c starts its transfers in 7-or 10-bit addressing mode when acting as a master. This bit exists in this register only if the I2C_DYNAMIC_TAR_UPDATE configuration parameter is set to 1.
11	0h RW	**SPECIAL:** This bit indicates whether software performs a General Call or START BYTE command. • 0 = ignore bit 10 GC_OR_START and use IC_TAR normally • 1 = perform special I2C command as specified in GC_OR_START bit
10	0h RW	**GC_OR_START:** If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.
9:0	55h RW	**IC_TAR:** This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

3.41.3 I2C Slave Address Register (IC_SAR)—Offset 8h

The IC SAR Address Register holds the slave address when the I2C is operating as a slave.

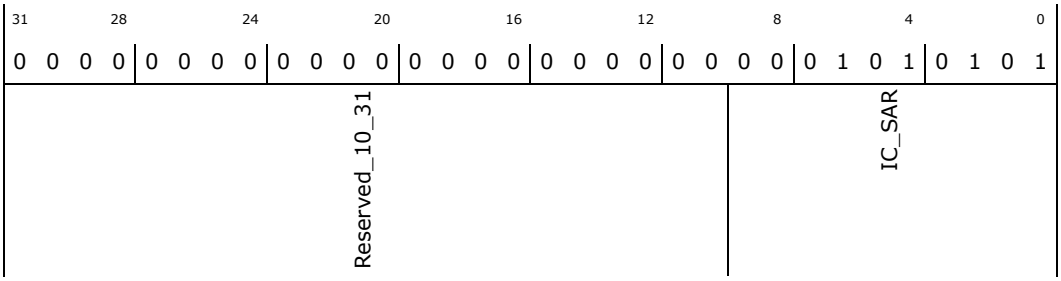
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_SAR: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:5] + 10h

Default: 00000055h



Bit Range	Default & Access	Description
31:10	0b RW	**Reserved_10_31:** Reserved.
9:0	55h RW	**IC_SAR:** The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.41.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

Note: It is not necessary to perform any write to this register if DW_apb_i2c is enabled as an I2C slave only.

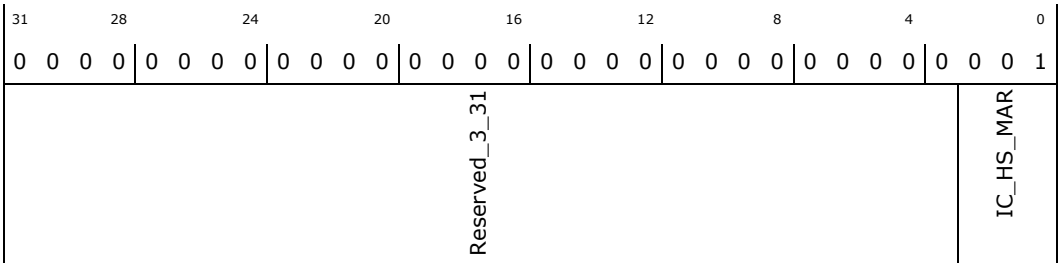
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_HS_MADDR: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:5] + 10h

Default: 00000001h



Bit Range	Default & Access	Description
31:3	0b RW	**Reserved_3_31:** Reserved.
2:0	1h RW	**IC_HS_MAR:** This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highs peed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register goes away and becomes read-only returning 0s if the IC_MAX_SPEED_MODE configuration parameter is set to either Standard (1) or Fast (2). This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.41.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

This is the register written to by the CPU when filling the TX FIFO, and read from by the CPU when retrieving bytes from RX FIFO.

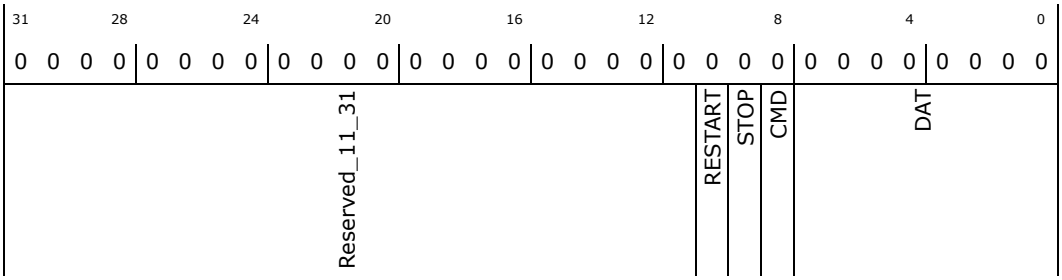
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_DATA_CMD: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:5] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:11	0b RW	**Reserved_11_31:** Reserved.

Bit Range	Default & Access	Description
10	0h RW	**RESTART:** This bit controls whether a RESTART is issued before the byte is sent or received. This bit is available only if IC_EMPTYFIFO_HOLD_MASTER_EN is configured to 1. 1 If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/ received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. 0 If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.
9	0h RW	**STOP:** This bit determines whether STOP is generated after a data byte is sent or received.
8	0h RW	**CMD:** This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It only controls the direction when it acts as a master. • 1 = Read • 0 = Write
7:0	0h RW	**DAT:** This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. When you read this register, however, these bits return the value of data received on the DW_apb_i2c interface.

3.41.10 High Speed I2C Clock SCL High Count Register (IC_HS_SCL_HCNT)—Offset 24h

This register must be set before any I2C bus transaction can take place, to ensure proper I/O timing. This register sets the SCL clock high-period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL. For more information, refer to *IC_CLK Frequency Configuration* .

The SCL High time depends on the loading of the bus. For 100pF loading, the SCL High time is 60ns; for 400pF loading, the SCL High time is 120ns.

This register goes away and becomes read-only if IC_MAX_SPEED_MODE!= high. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

The minimum valid value is 6; hardware prevents values less than this being written, and, if attempted, results in 6 being set. For designs with APB_DATA_WIDTH == 8 the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte can be programmed.

When the configuration parameter IC_HC_COUNT_VALUES is set to 1, this register is read only.

- The I2C is disabled
- There is a transmit abort -- that is, TX_ABRT bit is set in the IC_RAW_INTR_STAT register
- The slave bulk transmit mode is aborted

The register increments whenever data is placed into the transmit FIFO and decrements when data is taken from the transmit FIFO.

Access Method

3.41.32 I2C SDA Hold Time Length Register (IC_SDA_HOLD)—Offset 7Ch

This register controls the amount of hold time on the SDA signal after a negative edge of SCL in both master and slave mode, in units of ic_clk period. The value programmed must be greater than the minimum hold time in each mode for the value to be implemented one cycle in master mode, seven cycles in slave mode. Writes to this register succeed only when IC_ENABLE=0.

The programmed SDA hold time cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N_SCL_LOW-2, where N_SCL_LOW is the duration of the low part of the scl period measured in ic_clk cycles.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

15:0	1h RW	**IC_SDA_HOLD:** Sets the required SDA hold time in units of ic_clk period.

3.41.33 I2C Transmit Abort Source Register (IC_TX_ABRT_SOURCE)—Offset 80h

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

3.41.34 Generate Slave Data NACK Register (IC_SLV_DATA_NACK_ONLY)—Offset 84h

The register is used to generate a NACK for the data part of a transfer when DW_apb_i2c is acting as a slave-receiver. This register only exists when the IC_SLV_DATA_NACK_ONLY parameter is set to 1. When this parameter disabled, this register does not exist and writing to the registers address has no effect. A write can occur on this register if either of the following conditions are met.

- DW_apb_i2c is disabled (IC_ENABLE[0] = 0)
- Slave part is inactive (IC_STATUS[6] = 0)

NOTE = The IC_STATUS[6] is a register read-back location for the internal slv_activity signal; the user should poll this before writing the ic_slv_data_nack_only bit.

When the register is set to a value of 0, it generates NACK/ACK, depending on normal criteria. • 1 = generate NACK after data byte received • 0 = generate NACK/ACK normally

3.41.35 DMA Control Register (IC_DMA_CR)—Offset 88h

When DW_apb_i2c is not configured for DMA operation, this register does not exist and writing to the registers address has no effect and reading from this register address will return zero. The register is used to enable the DMA Controller interface operation. There is a separate bit for transmit and receive. This can be programmed regardless of the state of IC_ENABLE.

For instance, when DMARDL is 0, then dma_rx_req is asserted when 1 or more data entries are present in the receive FIFO.

3.41.38 I2C SDA Setup Register (IC_SDA_SETUP)—Offset 94h

This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL -- relative to SDA changing -- by holding SCL low when DW_apb_i2c services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2.

NOTE: The length of setup time is calculated using [(IC_SDA_SETUP - 1) * (ic_clk_period)], so if the user requires 10 ic_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the DW_apb_i2c when operating as a slave transmitter.

Access Method

3.41.40 I2C Enable Status Register (IC_ENABLE_STATUS)—Offset 9Ch

The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE register is set from 1 to 0, that is, when DW_apb_i2c is disabled.

3.43.1 I2C Control Register (IC_CON)—Offset 0h

If configuration parameter I2C_DYNAMIC_TAR_UPDATE = 0, all bits are Read/Write.

If I2C_DYNAMIC_TAR_UPDATE = 1, bit 4 is Read-only.

This register can be written only when the DW_apb_i2c is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

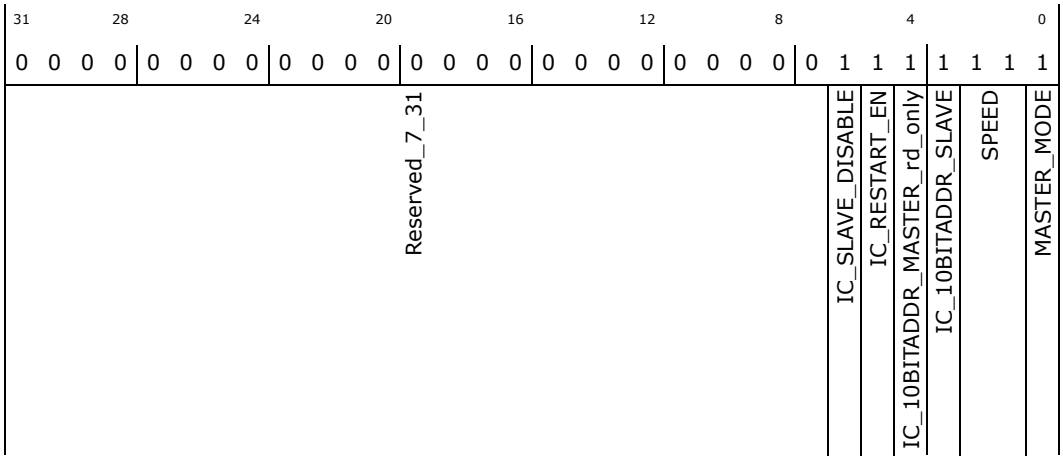
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_CON: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:6] + 10h

Default: 0000007Fh



Bit Range	Default & Access	Description
31:7	0b RW	**Reserved_7_31:** Reserved.
6	1h RW	**IC_SLAVE_DISABLE:** This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	1h RW	**IC_RESTART_EN:** Determines whether RESTART conditions may be sent when acting as a master. When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: • Sending a START BYTE • Performing any high-speed mode operation • Performing direction changes in combined format mode • Performing a read operation with a 10-bit address
4	1h RO	**IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only):** Controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register.
3	1h RW	**IC_10BITADDR_SLAVE:** When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.
2:1	3h RW	**SPEED:** These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	1h RW	**MASTER MODE (MASTER_MODE):** This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

3.43.2 I2C Target Address Register (IC_TAR)—Offset 4h

If the configuration parameter I2C_DYNAMIC_TAR_UPDATE is set to No (0), this register is 12 bits wide, and bits 15:12 are reserved. Writes to this register succeed only when IC_ENABLE is set to 0.

However, if I2C_DYNAMIC_TAR_UPDATE = 1, then the register becomes 13 bits wide. In this case, writes to IC_TAR succeed when one of the following conditions are true:

- DW_apb_i2c is NOT enabled (IC_ENABLE is set to 0)
-
- OR
-
- DW_apb_i2c is enabled (IC_ENABLE=1)
- AND

- DW_apb_i2c is NOT engaged in any Master (tx, rx) operation (IC_STATUS[5]=0)
- AND
- DW_apb_i2c is enabled to operate in Master mode (IC_CON[0]=1)
- AND
- There are NO entries in the TX FIFO (IC_STATUS[2]=1)

Access Method

BAR Type: PCI Configuration Register (Size: 32 bits)

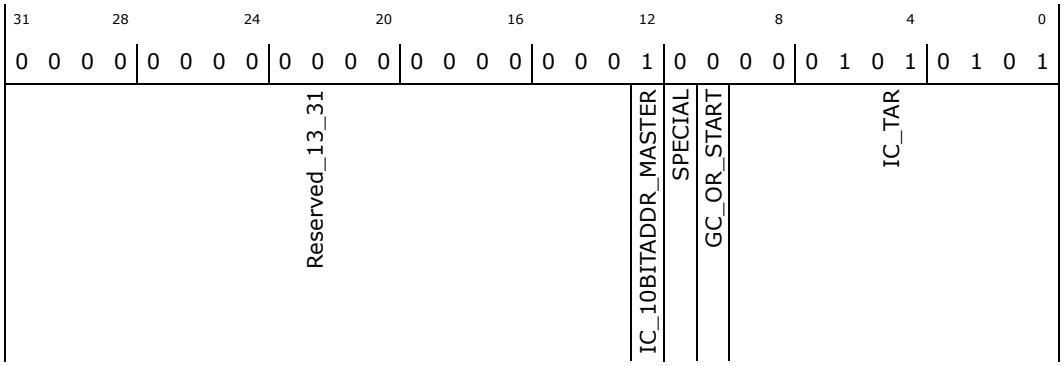
Default: 00001055h



Bit Range	Default & Access	Description
31:13	0b RW	**Reserved_13_31:** Reserved.
12	1h RW	**IC_10BITADDR_MASTER:** This bit controls whether the DW_apb_i2c starts its transfers in 7-or 10-bit addressing mode when acting as a master. This bit exists in this register only if the I2C_DYNAMIC_TAR_UPDATE configuration parameter is set to 1.
11	0h RW	**SPECIAL:** This bit indicates whether software performs a General Call or START BYTE command. • 0 = ignore bit 10 GC_OR_START and use IC_TAR normally • 1 = perform special I2C command as specified in GC_OR_START bit
10	0h RW	**GC_OR_START:** If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.
9:0	55h RW	**IC_TAR:** This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

3.43.3 I2C Slave Address Register (IC_SAR)—Offset 8h

The IC SAR Address Register holds the slave address when the I2C is operating as a slave.

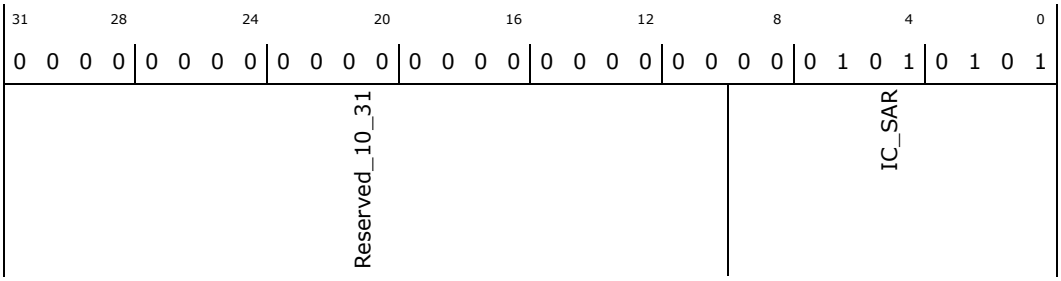
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_SAR: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:6] + 10h

Default: 00000055h



Bit Range	Default & Access	Description
31:10	0b RW	**Reserved_10_31:** Reserved.
9:0	55h RW	**IC_SAR:** The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.43.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

Note: It is not necessary to perform any write to this register if DW_apb_i2c is enabled as an I2C slave only.

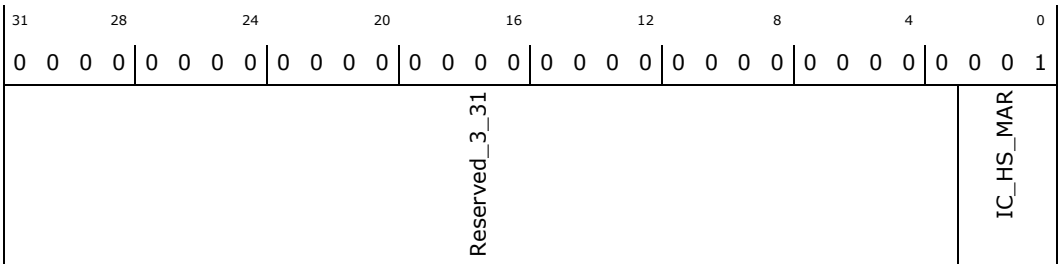
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_HS_MADDR: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:6] + 10h

Default: 00000001h



Bit Range	Default & Access	Description
31:3	0b RW	**Reserved_3_31:** Reserved.
2:0	1h RW	**IC_HS_MAR:** This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight high speed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register goes away and becomes read-only returning 0s if the IC_MAX_SPEED_MODE configuration parameter is set to either Standard (1) or Fast (2). This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.43.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

This is the register written to by the CPU when filling the TX FIFO, and read from by the CPU when retrieving bytes from RX FIFO.

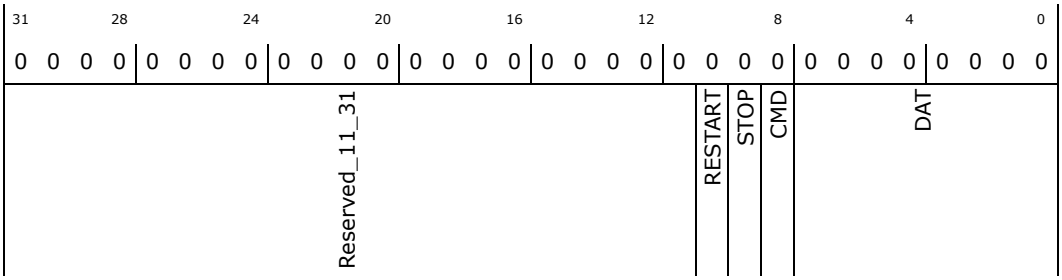
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_DATA_CMD: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:6] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:11	0b RW	**Reserved_11_31:** Reserved.

Bit Range	Default & Access	Description
10	0h RW	**RESTART:** This bit controls whether a RESTART is issued before the byte is sent or received. This bit is available only if IC_EMPTYFIFO_HOLD_MASTER_EN is configured to 1. 1 If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/ received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. 0 If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.
9	0h RW	**STOP:** This bit determines whether STOP is generated after a data byte is sent or received.
8	0h RW	**CMD:** This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It only controls the direction when it acts as a master. • 1 = Read • 0 = Write
7:0	0h RW	**DAT:** This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. When you read this register, however, these bits return the value of data received on the DW_apb_i2c interface.

3.43.10 High Speed I2C Clock SCL High Count Register (IC_HS_SCL_HCNT)—Offset 24h

This register must be set before any I2C bus transaction can take place, to ensure proper I/O timing. This register sets the SCL clock high-period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL. For more information, refer to *IC_CLK Frequency Configuration* .

The SCL High time depends on the loading of the bus. For 100pF loading, the SCL High time is 60ns; for 400pF loading, the SCL High time is 120ns.

This register goes away and becomes read-only if IC_MAX_SPEED_MODE!= high. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

The minimum valid value is 6; hardware prevents values less than this being written, and, if attempted, results in 6 being set. For designs with APB_DATA_WIDTH == 8 the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte can be programmed.

When the configuration parameter IC_HC_COUNT_VALUES is set to 1, this register is read only.

Bit Range	Default & Access	Description
11	0h RO	**R_GEN_CALL:** Set only when a General Call address is received and acknowledged. It stays set until it is cleared either by disabling DW_apb_i2c or when the CPU reads bit 0 of the IC_CLR_GEN_CALL register.

3.43.30 I2C Transmit FIFO Level Register (IC_TXFLR)—Offset 74h

This register contains the number of valid data entries in the transmit FIFO buffer. It is cleared whenever:

- The I2C is disabled
- There is a transmit abort -- that is, TX_ABRT bit is set in the IC_RAW_INTR_STAT register
- The slave bulk transmit mode is aborted

The register increments whenever data is placed into the transmit FIFO and decrements when data is taken from the transmit FIFO.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

3.43.31 I2C Receive FIFO Level Register (IC_RXFLR)—Offset 78h

This register contains the number of valid data entries in the receive FIFO buffer. The register is cleared by the following methods:

- The I2C is disabled
- Whenever there is a transmit abort caused by any of the events tracked in IC_TX_ABRT_SOURCE

The register increments whenever data is placed into the receive FIFO and decrements when data is taken from the receive FIFO.

8:0	0h RO	**Receive FIFO Level (RXFLR):** Contains the number of valid data entries in the receive FIFO.

3.43.32 I2C SDA Hold Time Length Register (IC_SDA_HOLD)—Offset 7Ch

This register controls the amount of hold time on the SDA signal after a negative edge of SCL in both master and slave mode, in units of ic_clk period. The value programmed must be greater than the minimum hold time in each mode for the value to be implemented one cycle in master mode, seven cycles in slave mode. Writes to this register succeed only when IC_ENABLE=0.

The programmed SDA hold time cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N_SCL_LOW-2, where N_SCL_LOW is the duration of the low part of the scl period measured in ic_clk cycles.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_SDA_HOLD: [BAR] + 7Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

15:0	1h RW	**IC_SDA_HOLD:** Sets the required SDA hold time in units of ic_clk period.

3.43.33 I2C Transmit Abort Source Register (IC_TX_ABRT_SOURCE)—Offset 80h

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

3.43.34 Generate Slave Data NACK Register (IC_SLV_DATA_NACK_ONLY)—Offset 84h

The register is used to generate a NACK for the data part of a transfer when DW_apb_i2c is acting as a slave-receiver. This register only exists when the IC_SLV_DATA_NACK_ONLY parameter is set to 1. When this parameter disabled, this register does not exist and writing to the registers address has no effect. A write can occur on this register if either of the following conditions are met.

- DW_apb_i2c is disabled (IC_ENABLE[0] = 0)
- Slave part is inactive (IC_STATUS[6] = 0)

NOTE = The IC_STATUS[6] is a register read-back location for the internal slv_activity signal; the user should poll this before writing the ic_slv_data_nack_only bit.

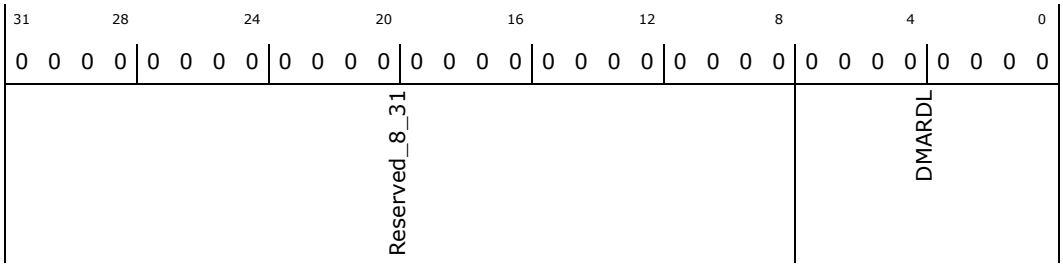
IC_DMA_RDLR: [BAR] + 90h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:6] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:8	0b RW	**Reserved_8_31:** Reserved.
7:0	0h RW	**Receive Data Level (DMARDL):** This bit field controls the level at which a DMA request is made by the receive logic. The watermark level = DMARDL+1; that is, dma_rx_req is generated when the number of valid data entries in the receive FIFO is equal to or more than this field value + 1, and RDMAE =1. For instance, when DMARDL is 0, then dma_rx_req is asserted when 1 or more data entries are present in the receive FIFO.

3.43.38 I2C SDA Setup Register (IC_SDA_SETUP)—Offset 94h

This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL -- relative to SDA changing -- by holding SCL low when DW_apb_i2c services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2.

NOTE: The length of setup time is calculated using [(IC_SDA_SETUP - 1) * (ic_clk_period)], so if the user requires 10 ic_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the DW_apb_i2c when operating as a slave transmitter.

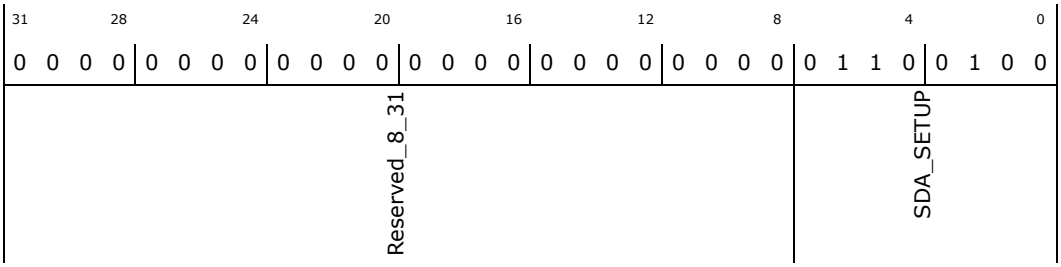
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_SDA_SETUP: [BAR] + 94h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:6] + 10h

Default: 00000064h



Bit Range	Default & Access	Description
31:8	0b RW	**Reserved_8_31:** Reserved.
7:0	64h RW	**SDA Setup (SDA_SETUP):** It is recommended that if the required delay is 1000ns, then for an ic_clk frequency of 10 MHz, IC_SDA_SETUP should be programmed to a value of 11.

3.43.39 I2C ACK General Call Register (IC_ACK_GENERAL_CALL)—Offset 98h

The register controls whether DW_apb_i2c responds with an ACK or NACK when it receives an I2C General Call address.

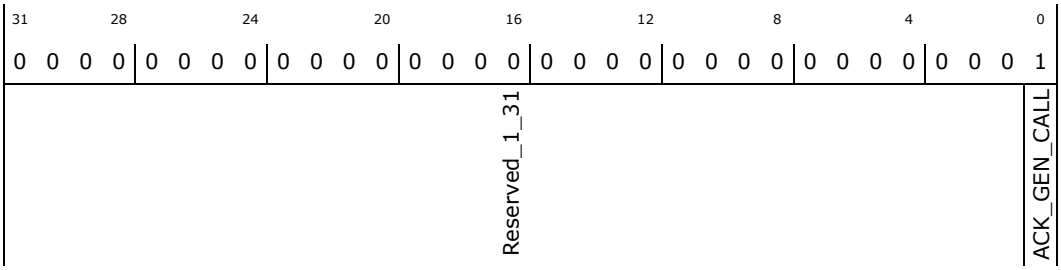
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_ACK_GENERAL_CALL: [BAR] + 98h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:6] + 10h

Default: 00000001h



Bit Range	Default & Access	Description
31:1	0b RW	**Reserved_1_31:** Reserved.
0	1h RW	**ACK General Call (ACK_GEN_CALL):** When set to 1, DW_apb_i2c responds with a ACK (by asserting ic_data_oe) when it receives a General Call. When set to 0, the DW_apb_i2c does not generate General Call interrupts.

3.43.40 I2C Enable Status Register (IC_ENABLE_STATUS)—Offset 9Ch

The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE register is set from 1 to 0, that is, when DW_apb_i2c is disabled.

- If IC_ENABLE has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.
- If IC_ENABLE has been set to 0, bits 2:1 will only be valid as soon as bit 0 is read as 0.

NOTE = When IC_ENABLE has been written with 0, a delay occurs for bit 0 to be read as 0 because disabling the DW_apb_i2c depends on I2C bus activities.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_ENABLE_STATUS: [BAR] + 9Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:6] + 10h

2	0h RO	**SLV_RX_DATA_LOST:** This bit indicates if a Slave-Receiver operation has been aborted with at least one data byte received from an I2C transfer due to the setting of IC_ENABLE from 1 to 0.
1	0h RO	**SLV_DISABLED_WHILE_BUSY:** This bit indicates if a potential or active Slave operation has been aborted due to the setting of the IC_ENABLE register from 1 to 0.
0	0h RO	**ic_en Status (IC_EN):** This bit always reflects the value driven on the output port ic_en. When read as 1, DW_apb_i2c is deemed to be in an enabled state. When read as 0, DW_apb_i2c is deemed completely inactive.

Default: 00000100h

Bit Range	Default & Access	Description
31:24	00h RO	**Max_Lat (MAX_LAT):** Value of 0 indicates device has no major requirements for the settings of latency timers.

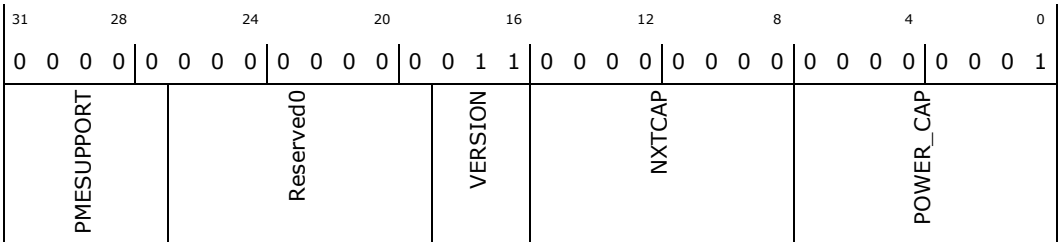
3.44.11 PowerManagement Capability ID (POWERCAPID)—Offset 80h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

POWERCAPID: [B:0, D:24, F:7] + 80h

Default: 00030001h



Bit Range	Default & Access	Description
31:27	00h RO	**PME_Support (PMESUPPORT):** This 5-bit field indicates the power states in which the function may assert PME#. A value of 0b for any bit indicates that the function is not capable of asserting the PME# signal while in that power state. • bit(11) X XXX1b - PME# can be asserted from D0. • bit(12) X XX1Xb - PME# can be asserted from D1. Bridge does not support this state. • bit(13) X X1XXb - PME# can be asserted from D2. Bridge does not support this state. • bit(14) X 1XXXb - PME# can be asserted from D3hot. • bit(15) 1 XXXXb - PME# can be asserted from D3cold. Bridge does not support this state. This field is taken from the strap strap_pme_support.
26:19	00h RO	**Reserved0:** Reserved.
18:16	3h RO	**Version (VERSION):** Indicates support for Revision 1.2 of the PCI Power Management Specification.

15	0h RW/1C	**PME Status (PMESTATUS):** • 0 = Software clears the bit by writing a 1 to it. • 1 = This bit is set when the AHB Device would normally assert the PME# signal independent of the state of the PME Enable bit (bit 8 in this register).

Bit Range	Default & Access	Description
14:9	00h RO	**Reserved1:** Reserved.
8	0h RW	**PME Enable (PMEENABLE):** A 1 enables the function to assert PME#. When 0, PME# message on SB is disabled.
7:4	0h RO	**Reserved2:** Reserved.
3	1h RO	**No_Soft_Reset (NO_SOFT_RESET):** This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved.
2	0h RO	**Reserved3:** Reserved.
1:0	0h RW	**Power State (POWERSTATE):** This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: • 00 = D0 state • 11 = D3HOT state • Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. 3.45.1 I2C Control Register (IC_CON)—Offset 0h

If configuration parameter I2C_DYNAMIC_TAR_UPDATE = 0, all bits are Read/Write.

If I2C_DYNAMIC_TAR_UPDATE = 1, bit 4 is Read-only.

This register can be written only when the DW_apb_i2c is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

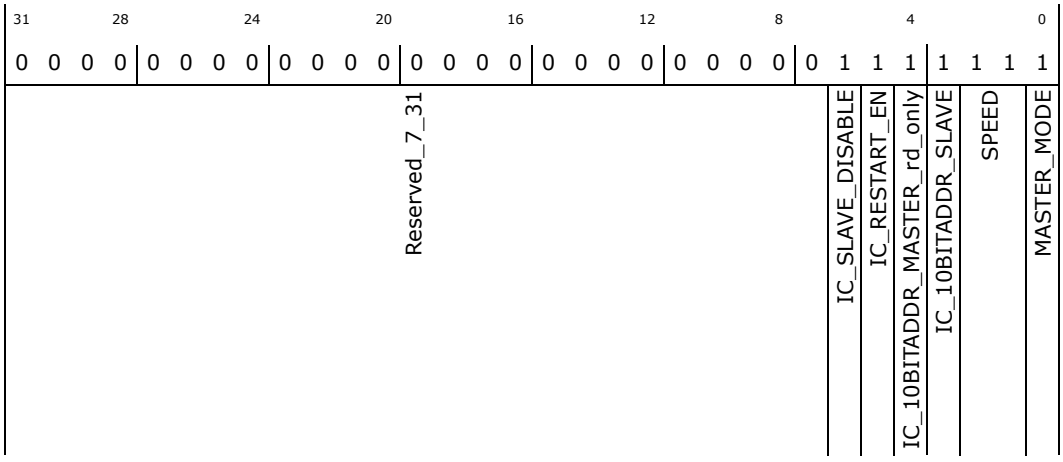
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_CON: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:7] + 10h

Default: 0000007Fh



Bit Range	Default & Access	Description
31:7	0b RW	**Reserved_7_31:** Reserved.
6	1h RW	**IC_SLAVE_DISABLE:** This bit controls whether I2C has its slave disabled. By default, the slave is always enabled (in reset state as well). If you need to disable it after reset, set this bit to 1. If this bit is set (slave is disabled), DW_apb_i2c functions only as a master and does not perform any action that requires a slave.
5	1h RW	**IC_RESTART_EN:** Determines whether RESTART conditions may be sent when acting as a master. When the RESTART is disabled, the DW_apb_i2c master is incapable of performing the following functions: • Sending a START BYTE • Performing any high-speed mode operation • Performing direction changes in combined format mode • Performing a read operation with a 10-bit address
4	1h RO	**IC_10BITADDR_MASTER (IC_10BITADDR_MASTER_rd_only):** Controls whether the DW_apb_i2c starts its transfers in 7- or 10-bit addressing mode when acting as a master. If I2C_DYNAMIC_TAR_UPDATE = 1, then this bit is read-only copy of bit 12 of IC_TAR register.
3	1h RW	**IC_10BITADDR_SLAVE:** When acting as a slave, this bit controls whether the DW_apb_i2c responds to 7- or 10-bit addresses.
2:1	3h RW	**SPEED:** These bits control at which speed the DW_apb_i2c operates; its setting is relevant only if one is operating the DW_apb_i2c in master mode. Hardware protects against illegal values being programmed by software. This register should be programmed only with a value in the range of 1 to IC_MAX_SPEED_MODE; otherwise, hardware updates this register with the value of IC_MAX_SPEED_MODE.
0	1h RW	**MASTER MODE (MASTER_MODE):** This bit controls whether the DW_apb_i2c master is enabled. Software should ensure that if this bit is set to X, then bit 6 should also be set to X.

3.45.2 I2C Target Address Register (IC_TAR)—Offset 4h

If the configuration parameter I2C_DYNAMIC_TAR_UPDATE is set to No (0), this register is 12 bits wide, and bits 15:12 are reserved. Writes to this register succeed only when IC_ENABLE is set to 0.

However, if I2C_DYNAMIC_TAR_UPDATE = 1, then the register becomes 13 bits wide. In this case, writes to IC_TAR succeed when one of the following conditions are true:

- DW_apb_i2c is NOT enabled (IC_ENABLE is set to 0)
-
- OR
-
- DW_apb_i2c is enabled (IC_ENABLE=1)
- AND

- DW_apb_i2c is NOT engaged in any Master (tx, rx) operation (IC_STATUS[5]=0)
- AND
- DW_apb_i2c is enabled to operate in Master mode (IC_CON[0]=1)
- AND
- There are NO entries in the TX FIFO (IC_STATUS[2]=1)

Access Method

IC_TAR: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)

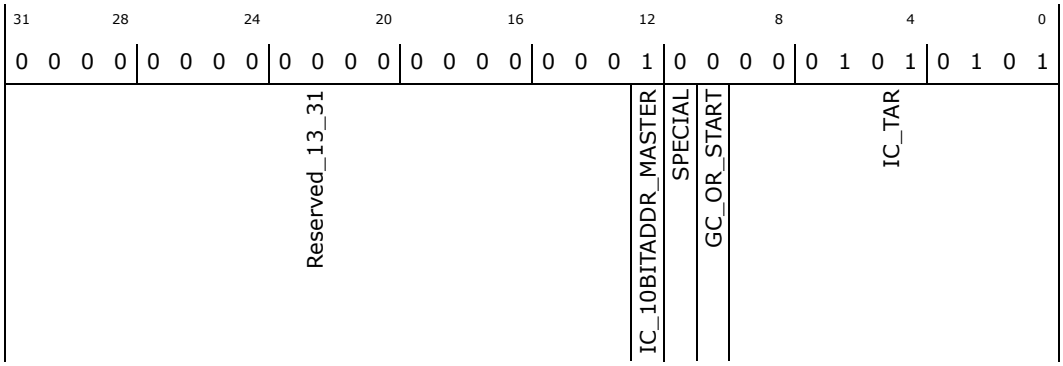
Default: 00001055h



Bit Range	Default & Access	Description
31:13	0b RW	**Reserved_13_31:** Reserved.
12	1h RW	**IC_10BITADDR_MASTER:** This bit controls whether the DW_apb_i2c starts its transfers in 7-or 10-bit addressing mode when acting as a master. This bit exists in this register only if the I2C_DYNAMIC_TAR_UPDATE configuration parameter is set to 1.
11	0h RW	**SPECIAL:** This bit indicates whether software performs a General Call or START BYTE command. • 0 = ignore bit 10 GC_OR_START and use IC_TAR normally • 1 = perform special I2C command as specified in GC_OR_START bit
10	0h RW	**GC_OR_START:** If bit 11 (SPECIAL) is set to 1, then this bit indicates whether a General Call(0) or START(1) byte command is to be performed by the DW_apb_i2c.
9:0	55h RW	**IC_TAR:** This is the target address for any master transaction. When transmitting a General Call, these bits are ignored. To generate a START BYTE, the CPU needs to write only once into these bits.

3.45.3 I2C Slave Address Register (IC_SAR)—Offset 8h

The IC SAR Address Register holds the slave address when the I2C is operating as a slave.

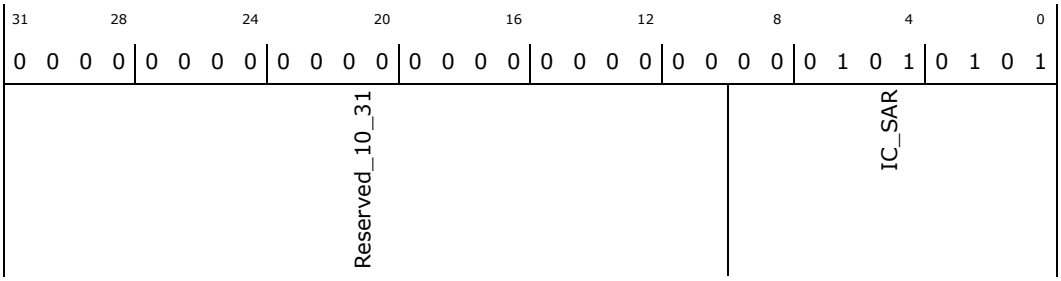
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_SAR: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:7] + 10h

Default: 00000055h



Bit Range	Default & Access	Description
31:10	0b RW	**Reserved_10_31:** Reserved.
9:0	55h RW	**IC_SAR:** The IC_SAR holds the slave address when the I2C is operating as a slave. For 7-bit addressing, only IC_SAR[6:0] is used. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.45.4 I2C High Speed Master Mode Code Address Register (IC_HS_MADDR)—Offset Ch

Note: It is not necessary to perform any write to this register if DW_apb_i2c is enabled as an I2C slave only.

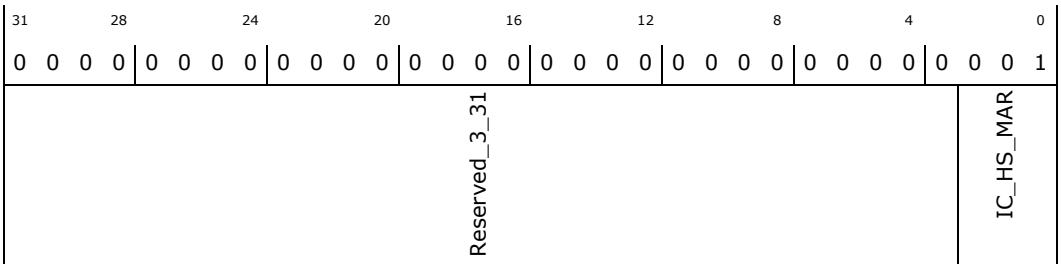
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_HS_MADDR: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:7] + 10h

Default: 00000001h



Bit Range	Default & Access	Description
31:3	0b RW	**Reserved_3_31:** Reserved.
2:0	1h RW	**IC_HS_MAR:** This bit field holds the value of the I2C HS mode master code. HS-mode master codes are reserved 8-bit codes (00001xxx) that are not used for slave addressing or other purposes. Each master has its unique master code; up to eight highspeed mode masters can be present on the same I2C bus system. Valid values are from 0 to 7. This register goes away and becomes read-only returning 0s if the IC_MAX_SPEED_MODE configuration parameter is set to either Standard (1) or Fast (2). This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.45.5 I2C Rx/Tx Data Buffer and Command Register (IC_DATA_CMD)—Offset 10h

This is the register written to by the CPU when filling the TX FIFO, and read from by the CPU when retrieving bytes from RX FIFO.

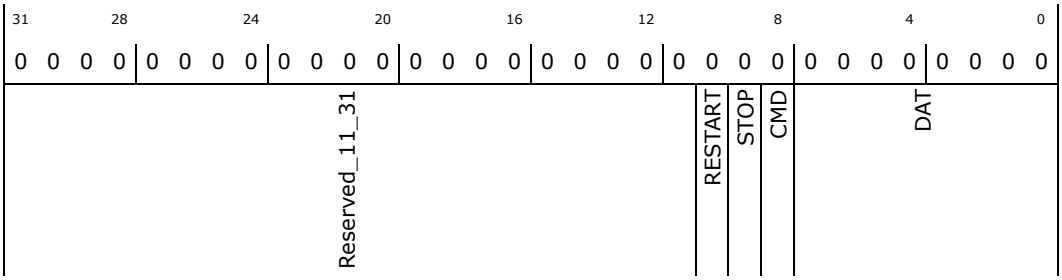
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_DATA_CMD: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:7] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:11	0b RW	**Reserved_11_31:** Reserved.

Bit Range	Default & Access	Description
10	0h RW	**RESTART:** This bit controls whether a RESTART is issued before the byte is sent or received. This bit is available only if IC_EMPTYFIFO_HOLD_MASTER_EN is configured to 1. 1 If IC_RESTART_EN is 1, a RESTART is issued before the data is sent/ received (according to the value of CMD), regardless of whether or not the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead. 0 If IC_RESTART_EN is 1, a RESTART is issued only if the transfer direction is changing from the previous command; if IC_RESTART_EN is 0, a STOP followed by a START is issued instead.
9	0h RW	**STOP:** This bit determines whether STOP is generated after a data byte is sent or received.
8	0h RW	**CMD:** This bit controls whether a read or a write is performed. This bit does not control the direction when the DW_apb_i2c acts as a slave. It only controls the direction when it acts as a master. • 1 = Read • 0 = Write
7:0	0h RW	**DAT:** This register contains the data to be transmitted or received on the I2C bus. If you are writing to this register and want to perform a read, bits 7:0 (DAT) are ignored by the DW_apb_i2c. When you read this register, however, these bits return the value of data received on the DW_apb_i2c interface.

3.45.10 High Speed I2C Clock SCL High Count Register (IC_HS_SCL_HCNT)—Offset 24h

This register must be set before any I2C bus transaction can take place, to ensure proper I/O timing. This register sets the SCL clock high-period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL. For more information, refer to *IC_CLK Frequency Configuration* .

The SCL High time depends on the loading of the bus. For 100pF loading, the SCL High time is 60ns; for 400pF loading, the SCL High time is 120ns.

This register goes away and becomes read-only if IC_MAX_SPEED_MODE!= high. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

The minimum valid value is 6; hardware prevents values less than this being written, and, if attempted, results in 6 being set. For designs with APB_DATA_WIDTH == 8 the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte can be programmed.

When the configuration parameter IC_HC_COUNT_VALUES is set to 1, this register is read only.

15:0	000ch RW	**High Speed I2C Clock SCL High Count Register (IC_HS_SCL_HCNT):** This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

3.45.11 High Speed I2C Clock SCL Low Count Register (IC_HS_SCL_LCNT)—Offset 28h

This register must be set before any I2C bus transaction can take place, to ensure proper I/O timing. This register sets the SCL clock low-period count for fast speed. It is used in high-speed mode to send the Master Code and START BYTE or General CALL. For more information, refer to *IC_CLK Frequency Configuration* in the Synopsis DesignWare DW_apb_i2c Databook.

The SCL High time depends on the loading of the bus. For 100pF loading, the SCL High time is 60ns; for 400pF loading, the SCL High time is 120ns.

This register goes away and becomes read-only if IC_MAX_SPEED_MODE!= high. This register can be written only when the I2C interface is disabled, which corresponds to the IC_ENABLE register being set to 0. Writes at other times have no effect.

The minimum valid value is 8; hardware prevents values less than this being written, and, if attempted, results in 8 being set. For designs with APB_DATA_WIDTH == 8 the order of programming is important to ensure the correct operation of the DW_apb_i2c. The lower byte must be programmed first. Then the upper byte can be programmed.

When the configuration parameter IC_HC_COUNT_VALUES is set to 1, this register is read only.

3.45.32 I2C SDA Hold Time Length Register (IC_SDA_HOLD)—Offset 7Ch

This register controls the amount of hold time on the SDA signal after a negative edge of SCL in both master and slave mode, in units of ic_clk period. The value programmed must be greater than the minimum hold time in each mode for the value to be implemented one cycle in master mode, seven cycles in slave mode. Writes to this register succeed only when IC_ENABLE=0.

The programmed SDA hold time cannot exceed at any time the duration of the low part of scl. Therefore the programmed value cannot be larger than N_SCL_LOW-2, where N_SCL_LOW is the duration of the low part of the scl period measured in ic_clk cycles.

Access Method

3.45.33 I2C Transmit Abort Source Register (IC_TX_ABRT_SOURCE)—Offset 80h

This register has 16 bits that indicate the source of the TX_ABRT bit. Except for Bit 9, this register is cleared whenever the IC_CLR_TX_ABRT register or the IC_CLR_INTR register is read. To clear Bit 9, the source of the ABRT_SBYTE_NORSTRT must be fixed first; RESTART must be enabled (IC_CON[5]=1), the SPECIAL bit must be cleared (IC_TAR[11]), or the GC_OR_START bit must be cleared (IC_TAR[10]). Once the source of the ABRT_SBYTE_NORSTRT is fixed, then this bit can be cleared in the same manner as other bits in this register. If the source of the ABRT_SBYTE_NORSTRT is not fixed before attempting to clear this bit, Bit 9 clears for one cycle and is then re-asserted.

3.45.34 Generate Slave Data NACK Register (IC_SLV_DATA_NACK_ONLY)—Offset 84h

The register is used to generate a NACK for the data part of a transfer when DW_apb_i2c is acting as a slave-receiver. This register only exists when the IC_SLV_DATA_NACK_ONLY parameter is set to 1. When this parameter disabled, this register does not exist and writing to the registers address has no effect. A write can occur on this register if either of the following conditions are met.

- DW_apb_i2c is disabled (IC_ENABLE[0] = 0)
- Slave part is inactive (IC_STATUS[6] = 0)

NOTE = The IC_STATUS[6] is a register read-back location for the internal slv_activity signal; the user should poll this before writing the ic_slv_data_nack_only bit.

Access Method

IC_SLV_DATA_NACK_ONLY: [BAR] + 84h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:7] + 10h

0	0h RW	**Generate NACK (NACK):** This NACK generation only occurs when DW_apb_i2c is a slave receiver. If this register is set to a value of 1, it can only generate a NACK after a data byte is received; hence, the data transfer is aborted and the data received is not pushed to the receive buffer. When the register is set to a value of 0, it generates NACK/ACK, depending on normal criteria. • 1 = generate NACK after data byte received • 0 = generate NACK/ACK normally

3.45.35 DMA Control Register (IC_DMA_CR)—Offset 88h

This register is only valid when DW_apb_i2c is configured with a set of DMA Controller interface signals (IC_HAS_DMA = 1). When DW_apb_i2c is not configured for DMA operation, this register does not exist and writing to the registers address has no effect and reading from this register address will return zero. The register is used to enable the DMA Controller interface operation. There is a separate bit for transmit and receive. This can be programmed regardless of the state of IC_ENABLE.

3.45.36 DMA Transmit Data Level Register (IC_DMA_TDLR)—Offset 8Ch

This register is only valid when the DW_apb_i2c is configured with a set of DMA interface signals (IC_HAS_DMA = 1). When DW_apb_i2c is not configured for DMA operation, this register does not exist, writing to its address has no effect, and reading from its address returns zero.

3.45.37 I2C Receive Data Level Register (IC_DMA_RDLR)—Offset 90h

This register is only valid when DW_apb_i2c is configured with a set of DMA interface signals(IC_HAS_DMA = 1). When DW_apb_i2c is not configured for DMA operation, this register does not exist, writing to its address has no effect, and reading from its address returns zero.

The watermark level = DMARDL+1; that is, dma_rx_req is generated when the number of valid data entries in the receive FIFO is equal to or more than this field value + 1, and RDMAE =1. For instance, when DMARDL is 0, then dma_rx_req is asserted when 1 or more data entries are present in the receive FIFO.

3.45.38 I2C SDA Setup Register (IC_SDA_SETUP)—Offset 94h

This register controls the amount of time delay (in terms of number of ic_clk clock periods) introduced in the rising edge of SCL -- relative to SDA changing -- by holding SCL low when DW_apb_i2c services a read request while operating as a slave-transmitter. The relevant I2C requirement is tSU:DAT (note 4) as detailed in the I2C Bus Specification. This register must be programmed with a value equal to or greater than 2.

NOTE: The length of setup time is calculated using [(IC_SDA_SETUP - 1) * (ic_clk_period)], so if the user requires 10 ic_clk periods of setup time, they should program a value of 11. The IC_SDA_SETUP register is only used by the DW_apb_i2c when operating as a slave transmitter.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

IC_SDA_SETUP: [BAR] + 94h

BAR Type: PCI Configuration Register (Size: 32 bits)

3.45.39 I2C ACK General Call Register (IC_ACK_GENERAL_CALL)—Offset 98h

31:1	0b RW	**Reserved_1_31:** Reserved.
0	1h RW	**ACK General Call (ACK_GEN_CALL):** When set to 1, DW_apb_i2c responds with a ACK (by asserting ic_data_oe) when it receives a General Call. When set to 0, the DW_apb_i2c does not generate General Call interrupts.

3.45.40 I2C Enable Status Register (IC_ENABLE_STATUS)—Offset 9Ch

The register is used to report the DW_apb_i2c hardware status when the IC_ENABLE register is set from 1 to 0, that is, when DW_apb_i2c is disabled.

- If IC_ENABLE has been set to 1, bits 2:1 are forced to 0, and bit 0 is forced to 1.
- If IC_ENABLE has been set to 0, bits 2:1 will only be valid as soon as bit 0 is read as 0.

NOTE = When IC_ENABLE has been written with 0, a delay occurs for bit 0 to be read as 0 because disabling the DW_apb_i2c depends on I2C bus activities.

The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	**Revision ID (RID):** Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

Bit Range	Default & Access	Description
31:8	0b RO	**RSVD0:** Reserved
7:6	0h RW	**FIFOSE_RCVR (RCVR):** RCVR Trigger. This is used to select the trigger level in the receiver FIFO at which the Received Data Available Interrupt is generated. In auto flow control mode it is used to determine when the rts_n signal is de-asserted. It also determines when the dma_rx_req_n signal is asserted in certain modes of operation. For details on DMA support, refer to DMA Support on page 43. The following trigger levels are supported: • 00 = 1 character in the FIFO • 01 = FIFO full • 10 = FIFO full • 11 = FIFO 2 less than full Reset Value: 0x0
5:4	0h RW	**Res_TET (TET):** TX Empty Trigger. Writes have no effect when THRE_MODE_USER == Disabled. This is used to select the empty threshold level at which the THRE Interrupts are generated when the mode is active. It also determines when the dma_tx_req_n signal is asserted when in certain modes of operation. For details on DMA support, refer to DMA Support on page 43. The following trigger levels are supported: • 00 = FIFO empty • 01 = 2 characters in the FIFO • 10 = FIFO full • 11 = FIFO full Reset Value: 0x0
3	0h RW	**IID3_DMAM (DMAM):** DMA Mode. This determines the DMA signalling mode used for the dma_tx_req_n and dma_rx_req_n output signals when additional DMA handshaking signals are not selected (DMA_EXTRA == No). For details on DMA support, refer to DMA Support on page 43. • 0 = mode 0 • 1 = mode 1 Reset Value: 0x0

Bit Range	Default & Access	Description
2	0h RW	**IID2_XFIFOR (XFIFOR):** XMIT FIFO Reset. This resets the control portion of the transmit FIFO and treats the FIFO as empty. This also de-asserts the DMA TX request and single signals when additional DMA handshaking signals are selected (DMA_EXTRA == YES). Note that this bit is 'self-clearing'. It is not necessary to clear this bit. Reset Value: 0x0
1	0h RW	**IID1_RFIFOR (RFIFOR):** RCVR FIFO Reset. This resets the control portion of the receive FIFO and treats the FIFO as empty. This also de-asserts the DMA RX request and single signals when additional DMA handshaking signals are selected (DMA_EXTRA == YES). Note that this bit is 'self-clearing'. It is not necessary to clear this bit. Reset Value: 0x0
0	1h RW	**FIFO Enable (FIFOE):** This enables/disables the transmit (XMIT) and receive (RCVR) FIFOs. Whenever the value of this bit is changed both the XMIT and RCVR controller portion of FIFOs is reset. Reset Value: 0x0

LCR: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:3] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:8	0b RO	**RSVD0:** Reserved
7	0h RW	**Divisor Latch Access Bit (DLAB):** If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This bit is used to enable reading and writing of the Divisor Latch register(DLL and DLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers. Reset Value: 0x0
6	0h RW	**Break Control Bit (Break):** This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] set to one) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low. Reset Value: 0x0

Bit Range	Default & Access	Description
5	0b RO	**RSVD1:** Reserved
4	0h RW	**Even Parity Select (EPS):** If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic 1s is transmitted or checked. If set to zero, an odd number of logic 1s is transmitted or checked. Reset Value: 0x0
3	0h RW	**Parity Enable (PEN):** If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero) -- otherwise always writable, always readable. This bit is used to enable and disable parity generation and detection in transmitted and received serial character respectively. • 0 = parity disabled • 1 = parity enabled Reset Value: 0x0
2	0h RW	**Number of Stop Bits (STOP):** If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This is used to select the number of stop bits per character that the peripheral transmits and receives. If set to zero, one stop bit is transmitted in the serial data. If set to one and the data bits are set to 5 (LCR[1:0] set to zero) one and a half stop bits is transmitted. Otherwise, two stop bits are transmitted. Note that regardless of the number of stop bits selected, the receiver checks only the first stop bit. • 0 = 1 stop bit • 1 = 1.5 stop bits when DLS (LCR[1:0]) is zero, else 2 stop bit Reset Value: 0x0
1:0	0h RW	**Data Length Select (DLS):** If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero) -- otherwise always writable, always readable. This is used to select the number of data bits per character that the peripheral transmits and receives. The number of bit that may be selected are as follows: • 00 = 5 bits • 01 = 6 bits • 10 = 7 bits • 11 = 8 bits Reset Value: 0x0

Bit Range	Default & Access	Description
31:6	0b RO	**RSVD0:** Reserved
5	0h RW	**Auto Flow Control Enable (AFCE):** Writeable only when AFCE_MODE == Enabled, always readable. When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, Auto Flow Control features are enabled as described in Auto Flow Control on page 37. • 0 = Auto Flow Control Mode disabled • 1 = Auto Flow Control Mode enabled Reset Value: 0x0
4	0h RW	**LoopBack Bit (LoopBack):** This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (SIR_MODE != Enabled or not active, MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. If operating in infrared mode (SIR_MODE == Enabled AND active, MCR[6] set to one), data on the sir_out_n line is held low, while serial data output is inverted and looped back to the sir_in line. 1	0h RW	**Request to Send (RTS):** This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFOs enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal is de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input. Reset Value: 0x0

Bit Range	Default & Access	Description
31:8	0b RO	**RSVD0:** Reserved

Bit Range	Default & Access	Description
7	0h RW	**Receiver FIFO Error Bit (RFE):** This bit is only relevant when FIFO_MODE != NONE AND FIFOs are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. • 0 = no error in RX FIFO • 1 = error in RX FIFO This bit is cleared when the LSR is read, the character with the error is at the top of the receiver FIFO, and there are no subsequent errors in the FIFO. Reset Value: 0x0
6	1h RW	**Transmitter Empty Bit (TEMT):** If in FIFO mode (FIFO_MODE != NONE) and FIFOs enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in non-FIFO mode or FIFOs are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty. Reset Value: 0x1
5	1h RW	**Transmit Holding Register Empty Bit (THRE):** If THRE_MODE_USER == Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting. For more details, see Programmable THRE Interrupt on page 40. Reset Value: 0x1
4	0h RW	**Break Interrupt Bit (BI):** This is used to indicate the detection of a break sequence on the serial input data. If in UART mode (SIR_MODE == Disabled), it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode (SIR_MODE == Enabled), it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit. In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read. Reset Value: 0x0

Bit Range	Default & Access	Description
3	0h RW	**Framing Error Bit (FE):** This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs, the UART tries to re synchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). • 0 = no framing error • 1 = framing error Reading the LSR clears the FE bit. Reset Value: 0x0
2	0h RW	**Parity Error Bit (PE):** This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). • 0 = no parity error • 1 = parity error Reading the LSR clears the PE bit. Reset Value: 0x0
1	0h RW	**Overrun Error Bit (OE):** This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost. • 0 = no overrun error • 1 = overrun error Reading the LSR clears the OE bit. Reset Value: 0x0
0	0h RW	**Data Ready Bit (DR):** This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. • 0 = no data ready • 1 = data ready This bit is cleared when the RBR is read in non-FIFO mode, or when the receiver FIFO is empty, in FIFO mode. Reset Value: 0x0

3	0h RW	**Delta Data Carrier Detect (DDCD):** This is used to indicate that the modem control line dcd_n has changed since the last time the MSR was read. • 0 = no change on dcd_n since last read of MSR • 1 = change on dcd_n since last read of MSR Reading the MSR clears the DDCD bit. In Loopback Mode (MCR[4] = 1), DDCD reflects changes on MCR[3] (Out2). Note, if the DDCD bit is not set and the dcd_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDCD bit is set when the reset is removed if the dcd_n signal remains asserted. Reset Value: 0x0
2	0h RW	**Trailing Edge of Ring Indicator (TERI):** This is used to indicate that a change on the input ri_n (from an active-low to an inactive-high state) has occurred since the last time the MSR was read. • 0 = no change on ri_n since last read of MSR • 1 = change on ri_n since last read of MSR Reading the MSR clears the TERI bit. In Loopback Mode (MCR[4] = 1), TERI reflects when MCR[2] (Out1) has changed state from a high to a low. Reset Value: 0x0
1	0h RW	**Delta Data Set Ready (DDSR):** This is used to indicate that the modem control line dsr_n has changed since the last time the MSR was read. • 0 = no change on dsr_n since last read of MSR • 1 = change on dsr_n since last read of MSR Reading the MSR clears the DDSR bit. In Loopback Mode (MCR[4] = 1), DDSR reflects changes on MCR[0] (DTR). Note, if the DDSR bit is not set and the dsr_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDSR bit is set when the reset is removed if the dsr_n signal remains asserted. Bit Range	Default & Access	Description
7:0	0h RW	**srbr_sthr0:** This is a shadow register for the RBR and has been allocated sixteen 32-bit locations to accommodate burst accesses from the master. This register contains the data byte received on the serial input port (sin) in UART mode or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If in non-FIFO mode (FIFO_MODE == NONE) or FIFOs are disabled (FCR[0] set to zero), the data in the RBR must be read before the next data arrives, otherwise it is overwritten, resulting in an overrun error. If in FIFO mode (FIFO_MODE != NONE) and FIFOs are enabled (FCR[0] set to one), this register accesses the head of the receive FIFO. 0	0h RW	**UART Busy (BUSY):** This bit is valid only when UART_16550_COMPATIBLE == NO and indicates that a serial transfer is in progress, ; when cleared, indicates that the DW_apb_uart is idle or inactive. • 0 = DW_apb_uart is idle or inactive • 1 = DW_apb_uart is busy (actively transferring data) NOTE: It is possible for the UART Busy bit to be cleared even though a new character may have been sent from another device. That is, if the DW_apb_uart has no data in THR and RBR and there is no transmission in progress and a start bit of a new character has just reached the DW_apb_uart. This is due to the fact that a valid start is not seen until the middle of the bit period and this duration is dependent on the baud divisor that has been programmed. If a second system clock has been implemented (CLOCK_MODE == Enabled), the assertion of this bit is also delayed by several cycles of the slower clock. Reset Value: 0x0

31:1	0b RO	**RSVD0:** Reserved
0	0h RW	**Shadow Request to Send (srts):** This is a shadow register for the RTS bit (MCR[1]), this can be used to remove the burden of having to performing a read-modify-write on the MCR. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the DW_apb_uart is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] = 0), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] = 1) and FIFOs enable (FCR[0] = 1), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). Note that in Loopback mode (MCR[4] = 1), the rts_n output is held inactive-high while the value of this location is internally looped back to an input. Reset Value: 0x0

3.47.33 Shadow Break Control Register (SBCR)—Offset 90h

This is a shadow register for the Break bit (LCR[6]), this can be used to remove the burden of having to performing a read modify write on the LCR. This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] = 1) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver. Reset Value: 0x0

31:8	000000h RO	**Class Code (CLASS_CODES):** The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	**Revision ID (RID):** Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

Bit Range	Default & Access	Description
31:8	0b RO	**RSVD0:** Reserved
7:6	0h RW	**FIFOSE_RCVR (RCVR):** RCVR Trigger. This is used to select the trigger level in the receiver FIFO at which the Received Data Available Interrupt is generated. In auto flow control mode it is used to determine when the rts_n signal is de-asserted. It also determines when the dma_rx_req_n signal is asserted in certain modes of operation. For details on DMA support, refer to DMA Support on page 43. The following trigger levels are supported: • 00 = 1 character in the FIFO • 01 = FIFO full • 10 = FIFO full • 11 = FIFO 2 less than full Reset Value: 0x0
5:4	0h RW	**Res_TET (TET):** TX Empty Trigger. Writes have no effect when THRE_MODE_USER == Disabled. This is used to select the empty threshold level at which the THRE Interrupts are generated when the mode is active. It also determines when the dma_tx_req_n signal is asserted when in certain modes of operation. For details on DMA support, refer to DMA Support on page 43. The following trigger levels are supported: • 00 = FIFO empty • 01 = 2 characters in the FIFO • 10 = FIFO full • 11 = FIFO full Reset Value: 0x0
3	0h RW	**IID3_DMAM (DMAM):** DMA Mode. This determines the DMA signalling mode used for the dma_tx_req_n and dma_rx_req_n output signals when additional DMA handshaking signals are not selected (DMA_EXTRA == No). For details on DMA support, refer to DMA Support on page 43. • 0 = mode 0 • 1 = mode 1 Reset Value: 0x0

Bit Range	Default & Access	Description
2	0h RW	**IID2_XFIFOR (XFIFOR):** XMIT FIFO Reset. This resets the control portion of the transmit FIFO and treats the FIFO as empty. This also de-asserts the DMA TX request and single signals when additional DMA handshaking signals are selected (DMA_EXTRA == YES). Note that this bit is 'self-clearing'. It is not necessary to clear this bit. Reset Value: 0x0
1	0h RW	**IID1_RFIFOR (RFIFOR):** RCVR FIFO Reset. This resets the control portion of the receive FIFO and treats the FIFO as empty. This also de-asserts the DMA RX request and single signals when additional DMA handshaking signals are selected (DMA_EXTRA == YES). Note that this bit is 'self-clearing'. It is not necessary to clear this bit. Reset Value: 0x0
0	1h RW	**FIFO Enable (FIFOE):** This enables/disables the transmit (XMIT) and receive (RCVR) FIFOs. Whenever the value of this bit is changed both the XMIT and RCVR controller portion of FIFOs is reset. Reset Value: 0x0

LCR: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:4] + 10h

Default: 00000000h

Bit Range	Default & Access	Description
31:8	0b RO	**RSVD0:** Reserved
7	0h RW	**Divisor Latch Access Bit (DLAB):** If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This bit is used to enable reading and writing of the Divisor Latch register(DLL and DLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers. Reset Value: 0x0
6	0h RW	**Break Control Bit (Break):** This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] set to one) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low. Reset Value: 0x0

Bit Range	Default & Access	Description
5	0b RO	**RSVD1:** Reserved
4	0h RW	**Even Parity Select (EPS):** If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic 1s is transmitted or checked. If set to zero, an odd number of logic 1s is transmitted or checked. Reset Value: 0x0
3	0h RW	**Parity Enable (PEN):** If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero) -- otherwise always writable, always readable. This bit is used to enable and disable parity generation and detection in transmitted and received serial character respectively. • 0 = parity disabled • 1 = parity enabled Reset Value: 0x0
2	0h RW	**Number of Stop Bits (STOP):** If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero); otherwise always writable, always readable. This is used to select the number of stop bits per character that the peripheral transmits and receives. If set to zero, one stop bit is transmitted in the serial data. If set to one and the data bits are set to 5 (LCR[1:0] set to zero) one and a half stop bits is transmitted. Otherwise, two stop bits are transmitted. Note that regardless of the number of stop bits selected, the receiver checks only the first stop bit. • 0 = 1 stop bit • 1 = 1.5 stop bits when DLS (LCR[1:0]) is zero, else 2 stop bit Reset Value: 0x0
1:0	0h RW	**Data Length Select (DLS):** If UART_16550_COMPATIBLE == NO, then writeable only when UART is not busy (USR[0] is zero) -- otherwise always writable, always readable. This is used to select the number of data bits per character that the peripheral transmits and receives. The number of bit that may be selected are as follows: • 00 = 5 bits • 01 = 6 bits • 10 = 7 bits • 11 = 8 bits Reset Value: 0x0

Bit Range	Default & Access	Description
31:6	0b RO	**RSVD0:** Reserved
5	0h RW	**Auto Flow Control Enable (AFCE):** Writeable only when AFCE_MODE == Enabled, always readable. When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, Auto Flow Control features are enabled as described in Auto Flow Control on page 37. • 0 = Auto Flow Control Mode disabled • 1 = Auto Flow Control Mode enabled Reset Value: 0x0
4	0h RW	**LoopBack Bit (LoopBack):** This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (SIR_MODE != Enabled or not active, MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. If operating in infrared mode (SIR_MODE == Enabled AND active, MCR[6] set to one), data on the sir_out_n line is held low, while serial data output is inverted and looped back to the sir_in line. 1	0h RW	**Request to Send (RTS):** This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFOs enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal is de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input. Reset Value: 0x0

Bit Range	Default & Access	Description
31:8	0b RO	**RSVD0:** Reserved

Bit Range	Default & Access	Description
7	0h RW	**Receiver FIFO Error Bit (RFE):** This bit is only relevant when FIFO_MODE != NONE AND FIFOs are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. • 0 = no error in RX FIFO • 1 = error in RX FIFO This bit is cleared when the LSR is read, the character with the error is at the top of the receiver FIFO, and there are no subsequent errors in the FIFO. Reset Value: 0x0
6	1h RW	**Transmitter Empty Bit (TEMT):** If in FIFO mode (FIFO_MODE != NONE) and FIFOs enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in non-FIFO mode or FIFOs are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty. Reset Value: 0x1
5	1h RW	**Transmit Holding Register Empty Bit (THRE):** If THRE_MODE_USER == Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting. For more details, see Programmable THRE Interrupt on page 40. Reset Value: 0x1
4	0h RW	**Break Interrupt Bit (BI):** This is used to indicate the detection of a break sequence on the serial input data. If in UART mode (SIR_MODE == Disabled), it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode (SIR_MODE == Enabled), it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit. In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read. Reset Value: 0x0

Bit Range	Default & Access	Description
3	0h RW	**Framing Error Bit (FE):** This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs, the UART tries to resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). • 0 = no framing error • 1 = framing error Reading the LSR clears the FE bit. Reset Value: 0x0
2	0h RW	**Parity Error Bit (PE):** This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). • 0 = no parity error • 1 = parity error Reading the LSR clears the PE bit. Reset Value: 0x0
1	0h RW	**Overrun Error Bit (OE):** This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost. • 0 = no overrun error • 1 = overrun error Reading the LSR clears the OE bit. Reset Value: 0x0
0	0h RW	**Data Ready Bit (DR):** This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. • 0 = no data ready • 1 = data ready This bit is cleared when the RBR is read in non-FIFO mode, or when the receiver FIFO is empty, in FIFO mode. Reset Value: 0x0

3	0h RW	**Delta Data Carrier Detect (DDCD):** This is used to indicate that the modem control line dcd_n has changed since the last time the MSR was read. • 0 = no change on dcd_n since last read of MSR • 1 = change on dcd_n since last read of MSR Reading the MSR clears the DDCD bit. In Loopback Mode (MCR[4] = 1), DDCD reflects changes on MCR[3] (Out2). Note, if the DDCD bit is not set and the dcd_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDCD bit is set when the reset is removed if the dcd_n signal remains asserted. Reset Value: 0x0
2	0h RW	**Trailing Edge of Ring Indicator (TERI):** This is used to indicate that a change on the input ri_n (from an active-low to an inactive-high state) has occurred since the last time the MSR was read. • 0 = no change on ri_n since last read of MSR • 1 = change on ri_n since last read of MSR Reading the MSR clears the TERI bit. In Loopback Mode (MCR[4] = 1), TERI reflects when MCR[2] (Out1) has changed state from a high to a low. Reset Value: 0x0
1	0h RW	**Delta Data Set Ready (DDSR):** This is used to indicate that the modem control line dsr_n has changed since the last time the MSR was read. • 0 = no change on dsr_n since last read of MSR • 1 = change on dsr_n since last read of MSR Reading the MSR clears the DDSR bit. In Loopback Mode (MCR[4] = 1), DDSR reflects changes on MCR[0] (DTR). Note, if the DDSR bit is not set and the dsr_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDSR bit is set when the reset is removed if the dsr_n signal remains asserted. Reset Value: 0x0

Bit Range	Default & Access	Description
7:0	0h RW	**srbr_sthr0:** This is a shadow register for the RBR and has been allocated sixteen 32-bit locations to accommodate burst accesses from the master. This register contains the data byte received on the serial input port (sin) in UART mode or the serial infrared input (sir_in) in infrared mode. The data in this register is valid only if the Data Ready (DR) bit in the Line status Register (LSR) is set. If in non-FIFO mode (FIFO_MODE == NONE) or FIFOs are disabled (FCR[0] set to zero), the data in the RBR must be read before the next data arrives, otherwise it is overwritten, resulting in an overrun error. If in FIFO mode (FIFO_MODE != NONE) and FIFOs are enabled (FCR[0] set to one), this register accesses the head of the receive FIFO. 0	0h RW	**UART Busy (BUSY):** This bit is valid only when UART_16550_COMPATIBLE == NO and indicates that a serial transfer is in progress, ; when cleared, indicates that the DW_apb_uart is idle or inactive. • 0 = DW_apb_uart is idle or inactive • 1 = DW_apb_uart is busy (actively transferring data) NOTE: It is possible for the UART Busy bit to be cleared even though a new character may have been sent from another device. That is, if the DW_apb_uart has no data in THR and RBR and there is no transmission in progress and a start bit of a new character has just reached the DW_apb_uart. This is due to the fact that a valid start is not seen until the middle of the bit period and this duration is dependent on the baud divisor that has been programmed. If a second system clock has been implemented (CLOCK_MODE == Enabled), the assertion of this bit is also delayed by several cycles of the slower clock. Reset Value: 0x0

31:1	0b RO	**RSVD0:** Reserved
0	0h RW	**Shadow Request to Send (srts):** This is a shadow register for the RTS bit (MCR[1]), this can be used to remove the burden of having to performing a read-modify-write on the MCR. This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the DW_apb_uart is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] = 0), the rts_n signal is set low by programming MCR[1] (RTS) to a high. In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] = 1) and FIFOs enable (FCR[0] = 1), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). Note that in Loopback mode (MCR[4] = 1), the rts_n output is held inactive-high while the value of this location is internally looped back to an input. Reset Value: 0x0

3.49.33 Shadow Break Control Register (SBCR)—Offset 90h

This is a shadow register for the Break bit (LCR[6]), this can be used to remove the burden of having to performing a read modify write on the LCR. This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] = 1) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver. Reset Value: 0x0

31:0	0b RW	**Message to PMC (MTPMC) (mtpmc):** A write to any of the bytes in this field causes an interrupt to the PMC. The PMC can read the contents of this register. The host must wait until the PMC has taken action on the previous write to MTPMC, as indicated by the PMC Message Full Status (PMC_MSG_1_FULL_STS) bit being cleared, before initiating another write to the MTPMC register. In the case of a message that involves a response from the PMC (such as a PMC XRAM read), the host must also consume any data returned by the PMC in the Message from PMC register (MFPMC) before initiating another message

24	0b RW	**UART Enable (UART_EN) (uart_en):** When set, PMC enables UART debug port

Bit Range	Default & Access	Description
23	0b RW	**DRAM Initialization Scratchpad Bit (DISB) (disb):** This bit does not effect hardware functionality in any way. It is provided as a scratchpad bit that is maintained through main power well resets and CF9h-initiated resets. BIOS is expected to set this bit prior to starting the DRAM initialization sequence and to clear this bit after completing the DRAM initialization sequence. BIOS can detect that a DRAM initialization sequence was interrupted by a reset by reading this bit during the boot sequence. If the bit is 1, then the DRAM initialization was interrupted. This bit is reset by the assertion of the RSMRST_B pin.
22	0b RO	**RSVD0:** Reserved
21	0b RO	**Memory Placed in Self-Refresh (MEM_SR) (mem_sr):** This bit will be set to 1 if DRAM should have remained powered and held in Self-Refresh through the last power state transition (i.e. the last time the system left S0). The scenarios where this should be the case are: - successful S3 entry and exit - successful Host partition reset without power cycle This bit will be cleared whenever the SOC begins a transition out of S0. Note: This bit should not be consulted upon wake from S1, as that state does not involve the same type of handshake or placing memory into Self-Refresh. It is assumed that software is already aware that memory context is not impacted by S1 and therefore does not need to check this bit. reset_type=global reset
20	0b RW	**System Reset Status (SRS) (srs):** SOC sets this bit when the PMU_RESETBUTTON_B# button is pressed. BIOS is expected to read this bit and clear it if it is set. This bit is also reset by RSMRST_B and CF9h resets. reset_type=Resume Well Reset#
19	0b RW	**CPU Thermal Trip Status (CTS) (cts):** This bit is set when the SOC thermal trip active while the system is in a valid state to honor the pin. This bit is also reset by RSMRST_B and CF9h resets. It is not reset by the shutdown and reboot associated with the thermal trip event. reset_type=Resume Well Reset#
18	0b RW	**Minimum PMU_SLP_S4_B Assertion Width Violation Status (MS4V) (ms4v):** Hardware sets this bit when the PMU_SLP_S4_B assertion width is less than the time programmed in the PMU_SLP_S4_B Minimum Assertion Width field. The SOC begins the timer when PMU_SLP_S4_B pin is asserted during S4/S5 entry, or when the RSMRST_B input is deasserted during SUS well power-up. The status bit is cleared by software writing a 1 to the bit. Note that this bit is functional regardless of the value in the PMU_SLP_S4_B Assertion Stretch Enable and the Disable-SLP_X-Stretching-After-SUS-Power-Failure bits. This bit is reset by the assertion of the RSMRST_B pin, but can be set in some cases before the default value is readable. reset_type=RSMRST_B
17	0b RO	**reserved3:** Reserved.
16	0b RW	**COREPWROK Failure (PWR_FLR) (pwr_flr):** Intel SOC sets this bit any time COREPWROK goes low if the system was in an S0 or S1 state. The bit will be cleared only by software writing a 1 back to the bit or by SUS well power loss. reset_type=global reset

Bit Range	Default & Access	Description
15	0b RW	**PME B0 S5 Disable (PME_B0_S5_DIS) (pme_b0_s5_dis):** When set to '1', this bit blocks wake events from PME_B0_STS in S5, regardless of the state of PME_B0_EN. When cleared (default), wake events from PME_B0_STS are allowed in S5 if PME_B0_EN = '1'. Wakes from power states other than S5 are not affected by this policy bit. The net effect of setting PME_B0_S5_DIS = '1' is described by the truth table below: Y = Wake N = Don't wake B0 = PME_B0_EN OV = WOL Enable Override B0/OV | S1/S3/S4 | S5 00 | N | N 01 | N | Y (LAN only) 11 | Y (all PME B0 sources) | Y (LAN only) 10 | Y (all PME B0 sources) | N This bit is cleared by the SRTCRST_B pin. reset_type=SRTCRST_B
14	1b RW	**SUS Well Power Failure (SUS_PWR_FLR) (sus_pwr_flr):** This bit is set to '1' whenever SUS well power is lost, as indicated by RSMRST_B assertion. Software writes a 1 to this bit to clear it. This bit is in the SUS well, and defaults to '1' based on RSMRST_B assertion (not cleared by any type of reset). Implementation Note: RSMRST_B is an asynchronous set term to this bit. reset_type=RSMRST_B
13	0b RW	**WOL Enable Override (WOL_EN_OVRD) (wol_en_ovrd):** When this bit is set to 1, the integrated LAN is enabled to wake the system from S5 regardless of the value in the PME_B0_EN bit in the GPE0a_EN register. This allows the system BIOS to enable Wake-On-LAN regardless of the policies selected through the operating system. This bit is maintained in the RTC power well, therefore permitting WOL following a surprise power failure even in cases in which the system may have been running in S0 without the PME Enables set. (Note that the LAN NVRAM configuration must support WOL after SUS power loss.) When this bit is cleared to 0, the wake-on-LAN policies are determined by OS-visible bits. This bit has no effect on wakes from S1, S3, or S4. This bit is cleared by the SRTCRST_B pin reset_type=SRTCRST_B
12	0b RW	**Disable SLP_X Stretching After SUS Well Power Up (DIS_SLP_X_STRCH_SUS_UP) (dis_slp_x_strch_sus_up):** When this bit is set to 1, all SLP_* pin stretching is disabled when powering up after a SUS well power loss. When this bit is left at 0, SLP_* stretching will be performed after SUS power failure as enabled in various other fields. Note that if this bit is a 0, SLP_* stretch timers start on SUS well power up (the SOC has no ability to count stretch time while the SUS well is powered down). Setting this bit can therefore prevent long delays after SUS power loss which may be common in mobile platforms and in manufacturing flow testing, while still allowing for the full power cycling during S3, S4 and S5 states. If the platform guarantees minimum SUS power down residence in other ways, an additional SOC-induced delay is not needed or wanted. This field is not writable when the SLP_Sx# Stretching Policy Lock-Down bit is set. This bit is cleared by the SRTCRST_B pin.
11:10	0b RW	**PMU_SLP_S3_B Minimum Assertion Width (SLP_S3_MIN_ASST_WDTH) (slp_s3_min_asst_wdth):** This 2-bit value indicates the minimum assertion width of the PMU_SLP_S3_B signal to guarantee that the Main power supplies have been fully power-cycled. This value may be modified per platform depending on power supply capacitance, board capacitance, power failure detection circuits, etc. Settings are: 00: 60 usec 01: 1 ms 10: 50 ms 11: 2 sec This field is not writable when the SLP_Sx# Stretching Policy Lock- Down bit is set. This bit is cleared by the RSMRST_B pin. reset_type=RSMRST_B

Bit Range	Default & Access	Description
9	0b RW	**General Reset Status (GEN_RST_STS) (gen_rst_sts):** This bit is set by hardware whenever PMU_PLTRST asserts for any reason other than going into a software-entered sleep state (via PM1_CNT.SLP_EN write). This bit is an optional tool to help BIOS determine when a reset might have collided with a wake from a valid sleep state. A possible usage model would be to consult and then write a '1' to clear this bit during the boot flow before determine what action to take based on reading PM1_STS.WAK_STS = '1'. If GEN_RST_STS = '1', the cold reset boot path could be followed rather than the resume path, regardless of the setting of WAK_STS. This bit does not affect SOC operation in any way, and can therefore be left set if BIOS chooses not to use it. This bit is set by global reset. reset_type=global reset
8	0b RW	**RTC_reserved (rtc_reserved):** reset_type=SRTCRST_B
7:6	0b RW	**SWSMI Rate Select (SWSMI_RATESEL) (swsmi_ratesel):** This 2-bit value indicates when the SWSMI timer will time out. Valid values are: 00 1.5ms +/- 0.6ms 01 16ms +/- 4ms 10 32ms +/- 4ms 11 64ms +/- 4ms These bits are not cleared by any type of reset except SRTCRST_B. Implementation Note: SWSMI is generated based on the internal free-running 1ms tick (to be accurate, it is 0.983ms/tick generated from 30ns * 2^15). Since the tick is free-running, the accuracy is within the following range. # of 0.983ms tick count SWSMI range 64ms SWSMI 62 -to- 63 60.946ms -to- 61.929ms 32ms SWSMI 31 -to- 32 30.473ms -to- 31.456ms 16ms SWSMI 15 -to- 16 14.745ms -to- 15.728ms 1.5ms SWSMI 1 -to- 2 0.983ms -to- 1.966ms reset_type=SRTCRST_B
5:4	0b RW	**PMU_SLP_S4_B Minimum Assertion Width (S4MAW) (s4maw):** This 2-bit value indicates the minimum assertion width of the PMU_SLP_S4_B signal to guarantee that the DRAMs have been safely power-cycled. This value may be modified per platform depending on DRAM types, power supply capacitance, etc. Valid values are: - 11: 1 second - 10: 2 seconds - 01: 3 seconds - 00: 4 seconds This value is used in two ways: 1. If the PMU_SLP_S4_B assertion width is ever shorter than this time, a status bit is set for BIOS to read when S0 is entered 2. If enabled by bit 3 in this register, the hardware will prevent the PMU_SLP_S4_B signal from deasserting within this minimum time period after asserting. Note that the logic that measures this time is in the suspend power well. Therefore, when leaving a G3 state, the minimum time is measured from the deassertion of the internal suspend well reset (unless the Disable SLP_X Stretching After SUS Power Failure bit is set). This field is not writable when the SLP_Sx# Stretching Policy Lock-Down bit is set. SRTCRST_B forces this field to the conservative default state (00b). reset_type=SRTCRST_B

Bit Range	Default & Access	Description
3	0b RW	**PMU_SLP_S4_B Assertion Stretch Enable (S4ASE) (s4ase):** When set to 1, the PMU_SLP_S4_B pin will minimally assert for the time specified in bits 5:4 of this register. This bit is provided so that all DIMMs in the system can deterministically detect a power-cycle event for proper initialization. Note that there are behavioral changes that may be noticeable to the end-user when this bit is set. Resume times from S4 and S5 and power-up times from G3 may be delayed by several seconds. Cases in which this feature may not be desirable and therefore keeping the bit cleared are: - A customer decides the user confusion due to the hardware delay is a bigger issue than the potential DRAM issue - A customer decides the software status bit solution is adequate - A different DRAM type is used or the platform provides an external solution to solve the power-cycling issue - Validation regressions are impacted by the delay (especially after RSMRST_B deassertion) - Avoid potential resume time WHQL violations This bit is not writable when the SLP_Sx# Stretching Policy Lock-Down bit is set. This bit is cleared by SRTCRST_B. reset_type=SRTCRST_B
2	1b RW	**RTC_PWR_STS (RPS) (rps):** Intel SOC will set this bit to 1 when RTEST_B indicates a weak or missing battery. The bit will remain set until the software clears it by writing a 0 back to this bit position. This bit is not cleared by any type of reset. reset_type=RTEST_B
1	0b RO	**reserved:** Reserved.
0	0b RW	**AFTERG3_EN (AG3E) (ag3e):** Determines what state to go to when power is reapplied after a power failure (G3 state). 0 = System will return to an S0 state (boot) after power is re-applied. 1 = System will return to the S5 state (except if it was in S4, in which case it will return to S4-like state). In the S5 state, the only enabled wake-up event is the Power Button or any enabled wake event that was preserved through the power failure. This bit is in the RTC well and is only cleared by SRTCRST_B assertion. reset_type=SRTCRST_B

3.55.15 ETR - Extended Test Mode Register (ETR)—Offset 48h

This register resides in the resume well. All bits except bit[23:16] are reset by internal Resume Well Reset. Bit[23:16] are reset by RSMRST_B only.

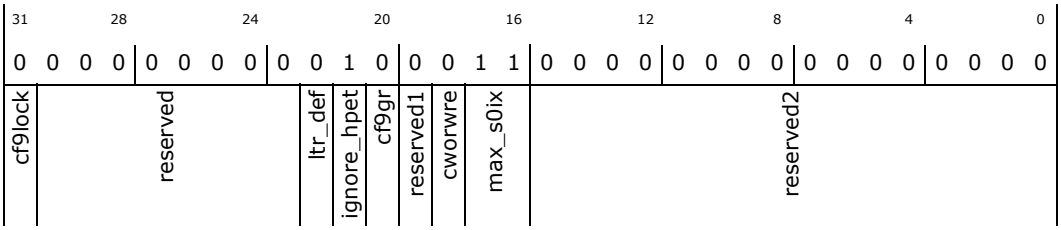
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

ETR: [PMC_BASE_ADDRESS] + 48h

PMC_BASE_ADDRESS Type: PCI Configuration Register (Size: 32 bits)
PMC_BASE_ADDRESS Reference: [B:0, D:31, F:0] + 44h

Default: 00230000h



Bit Range	Default & Access	Description
31	0b RW	**CF9h Lockdown (CF9LOCK) (cf9lock):** When set, this will lock the CF9h-Global-Reset bit. When set, this register locks itself. This register is reset by a CF9h reset.
30:23	0b RO	**reserved:** Reserved.
22	0b RW	**LTR default (LTR_DEF) (ltr_def):** When this bit is cleared, PMC will assume low LTR by default. When set, PMC will assume high LTR by default
21	1b RW	**Ignore HPET When going to S0i2 (IGNORE_HPET) (ignore_hpet):** When this bit is set, PMC will not check for HPET disabled before going to S0i2
20	0b RW	**CF9h Global Reset (CF9GR) (cf9gr):** When this bit is set, a CF9h write of 6h or Eh will cause a Global Reset of the Host partition. If this bit is cleared, a CF9h write of 6h or Eh will only reset the Host partition. It is recommended that BIOS should set this bit early on in the boot sequence, and then clear it and set the CF9LOCK bit prior to loading the OS. When this bit is set, the hardware assumes that bit 18 (CF9h Without Resume Well Reset Enable) is cleared. This register is locked by the CF9 Lockdown (CF9LOCK) bit. This register is not reset by a CF9h reset. reset_type=RSMRST_B
19	0b RO	**reserved (reserved1):** Reserved.

Bit Range	Default & Access	Description
18	0b RW	**CF9h Without Resume Well Reset Enable (CWORWRE) (cworwre):** When this bit is set, a CF9h write of 6h or Eh will not cause internal Resume Well Reset (WrsmrstB) to be asserted and thus resume well logic will maintain its state. When this bit is cleared, CF9h write of 6h or Eh will also reset resume well logic. This bit is to be used when a second reset through CF9 write is desired upon power up or after resume from low power states. This bit has to be set prior to the write to CF9 register and has to be cleared upon completing the reset. Failing to do so prevents resume well registers from being reset in the future CF9 writes. reset_type=RSMRST_B
17:16	11b RW	**MAX_S0IX (MAX_S0IX (max_s0ix):** Indicated the maximum S0i state SOC can go

PMC_BASE_ADDRESS Type: PCI Configuration Register (Size: 32 bits)

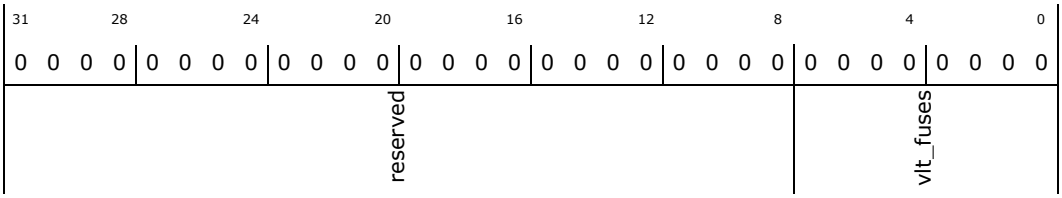
Default: 00000000h



Bit Range	Default & Access	Description
31:0	0b RW	**GPIO Rout (GPIO_ROUT) (gpio_rout):** Bits [15:0] determines GPIO SUS events rout. Bits [31:16] determines GPIO CORE events rout. Bits [1:0] determines GPIO SUS event 0. Bits [3:2] determines GPIO SUS event 1 and so on. Bits [17:16] determines GPIO CORE event 0. Bits [19:18] determines GPIO CORE event 1 and so on. If the corresponding GPIO is implemented and is set to an input, a '1' in the GP_LVL bit can be routed to cause an interrupt. If the GPIO is not set to an input, this field has no effect. * 00 No effect (or GPIO unimplemented), * 01 SMI# (if corresponding ALT_GPIO_SMI bit also set), * 10 SCI (if corresponding GPE0a_EN bit also set), * 11 Reserved If the system is in an S0-S5 state and if the GPE0a_EN bit is also set, then the GPIO can cause a Wake event, even if the GPIO is NOT routed to cause an interrupt. Exception: If the system is in S5 state due to a powerbutton override, then the GPIO's will not cause wake events. Note: Core well GPIO's are not capable of waking the system from sleep states where the core well is not powered.

3	0b RW	**Full Reset (FULL_RST) (full_rst):** When this bit is set to 1 and bit 1 is set to 1 (indicating Hard Reset, not Soft Reset), and the RST_CPU bit (bit 2) is written from 0 to 1, the PMC will do a full reset, including driving PMU_SLP_S3_B and PMU_SLP_S4_B active (low) for at least 3 (and no more than 5) seconds. When this bit is set, it also causes the full power cycle (PMU_SLP_S3/4_B assertion) in response to PMU_RESETBUTTON_B, COREPWROK, and Watchdog timer reset sources.
2	0b RW	**Reset CPU (RST_CPU) (rst_cpu):** This bit will cause either a hard or soft reset to the CPU depending on the state of the SYS_RST bit (bit 1 in this same register). The software will cause the reset by setting bit 2 from a 0 to a 1.
1	0b RW	**System Reset (SYS_RST) (sys_rst):** This bit determines the type of reset caused via RST_CPU (bit 2 of this register). If SYS_RST is 0 when RST_CPU goes from 0 to 1, then the PMC will force INIT# active for 16 PCI clocks. If SYS_RST is 1 when RST_CPU goes from 0 to 1, then the PMC will force PCI reset active for about 1 ms, however the PMU_SLP_S3_B and PMU_SLP_S4_B signals assertion is dependent on the value of the FULL_RST (bit3 of this register).

If system was in S1-S5, no wake even occurs. 1 0 SMI#. If system was in S1-S5, then a wake event occurs before the SMI#. 1 1 SCI. If system was in S1-S5, then a wake event occurs before the SCI. Note: This bit needs to be backed by the RTC well to allow an RTC event to wake after a power failure. In addition to being reset by SRTCRST_B assertion, PMC also clears this bit due to certain events: - Power button override - CPU thermal trip reset_type=SRTCRST_B
25	0b RO	**reserved6:** Reserved.
24	0b RW	**Power Button Enable (PWRBTN_EN) (pwrbtn_en):** This bit is the power button enable. 21	0b RW	**Global Enable (GBL_EN) (gbl_en):** The global enable bit. When both the GBL_EN and the GBL_STS are set, PMC generates an SCI. reset_type=PMU_PLTRST_B

Bit Range	Default & Access	Description
16	0b RW	**Timer Overflow Interrupt Enable (TMROF_EN) (tmrof_en):** This is the timer overflow interrupt enable bit. It works in conjunction with the SCI_EN bit: TMROF_EN SCI_EN Effect when TMROF_STS is set 0 x No SMI# or SCI. . 1 0 SMI#. 1 1 SCI. reset_type=PMU_PLTRST_B
15	0b RW	**Wake Status (WAK_STS) (wak_sts):** This bit is set when the system is in one of the Sleep states (via the SLP_EN bit) and an enabled Wake event occurs. Upon setting this bit, the PMC will transition the system to the ON state. This bit can only be set by hardware and can only be cleared by writing a one to this bit position. This bit is not affected by hard resets caused by a CF9 write, but is reset by RSMRST_B. If a power failure occurs (such as removed batteries) without the SLP_EN bit set, the WAK_STS bit will not be set when the power returns if the AFTER_G3 bit is 0. If the AFTER_G3 bit is 1, then the WAK_STS bit will be set after waking from a power failure. If necessary, the BIOS can clear the WAK_STS bit in this case This is based on discussions with Microsoft. That behavior is not in the ACPI spec. reset_type=RSMRST_B
14	0b RW	**PCI Express Wake Status (PCIEXP_WAKE_STS) (pciexp_wake_sts):** This bit is set by hardware to indicate that the system woke due to a PCI Express wakeup event. This event can be caused by the PCI Express WAKE# pins (PMU_WAKE_B, PCI_WAKE1_B, PCI_WAKE2_B, PCI_WAKE3_B) being active, or one or more of the PCI Express ports being in beacon state, or receipt of a PCI Express PME message at root port. This bit should only be set when one of these events causes the system to transition from a non-S0 system power state to the S0 system power state. This bit is set independent of the PCIEXP_WAKE_DIS bit. Software writes a 1 to clear this bit. If one of the WAKE# pins is still active during the write or one or more PCI Express ports is in the beacon state or PME message received indication is not cleared in the root port, then the bit will remain Power Management active (i.e. all inputs to this bit are level sensitive) Note: This bit does not itself cause a wake event or prevent entry to a sleeping state. Thus if the bit is 1 and the system is put into a sleeping state, the system will not automatically wake. reset_type=pmc_global_rst_b
13	0b RW	**USB clockless Wake Status (USB_CLKLESS_STS) (usb_clkless_sts):** This bit is set by hardware to indicate that the system woke due to change in USB serial lines. This bit is set independent of the USB_CLKLESS_EN bit. Software writes a 1 to clear this bit. reset_type=pmc_global_rst_b
12	0b RO	**reserved:** Reserved.
11	0b RW	**Power Button Override (PWRBTNOR_STS) (pwrbtnor_sts):** This bit is set any time a Power Button Override Event occurs (i.e. the power button is pressed for at least 4 consecutive seconds), or due to an internal thermal sensor catastrophic condition. These events cause an unconditional transition to the S5 state. The BIOS or SCI handler clears this bit by writing a 1 to it. This bit is not affected by hard resets via CF9h writes, and is not reset by RSMRST_B. Thus, this bit is preserved through power failures. Note that this bit is still asserted when the global SCI_EN is set to '1' then an SCI will be generated. reset_type=SRTCRST_B

Bit Range	Default & Access	Description
10	0b RW	**RTC Status (RTC_STS) (rtc_sts):** This bit is set when the RTC generates an alarm (assertion of the IRQ8# signal), and is not affected by any other enable bit. See RTC_EN for the effect when RTC_STS goes active. This bit is only set by hardware and can only be reset by writing a one to this bit position. This bit is not affected by hard resets caused by a CF9 write, but is reset by RSMRST_B. reset_type=RSMRST_B
9	0b RO	**reserved1:** Reserved.
8	0b RW	**Power Button Status (PWRBTN_STS) (pwrbtn_sts):** This bit is set when the PMU_PWRBTN_B signal is asserted (low), independent of any other enable bit. See PWRBTN_EN for the effect when PWRBTN_STS goes active. PWRBTN_STS is always a wake event. This bit is only set by hardware and can be cleared by software writing a one to this bit position. This bit is not affected by hard resets caused by a CF9 write, but is reset by RSMRST_B. If the PMU_PWRBTN_B signal is held low for more than 4 seconds, the PMC clears the PWRBTN_STS bit, sets the PWRBTNOR_STS bit, the system transitions to the S5 state, and only PMU_PWRBTN_B is enabled as a wake event. If PWRBTN_STS bit is cleared by software while the PMU_PWRBTN_B pin is still held low, this will not cause the PWRBTN_STS bit to be set. The PMU_PWRBTN_B signal must go inactive and active again to set the PWRBTN_STS bit. Note that the CPU Thermal Trip and the Internal Thermal Sensors' Catastrophic Condition result in behavior matching the Powerbutton Override, which includes clearing this bit. reset_type=RSMRST_B
7:6	0b RO	**reserved2:** Reserved.
5	0b RW	**GBL Status (GBL_STS) (gbl_sts):** This bit is set when an SCI is generated due to the BIOS wanting the attention of the SCI handler. BIOS has a corresponding bit, BIOS_RLS, which will cause an SCI and set this bit. The SCI handler should then clear this bit by writing a 1 to it. This bit will not cause wake events or SMI#. This bit is not effected by SCI_EN. Note: GBL_STS being set will cause an SCI, even if the SCI_EN bit is not set. Software must take great care not to set the BIOS_RLS bit (which causes GBL_STS to be set) if the SCI handler is not in place. reset_type=PMU_PLTRST_B
4:1	0b RO	**reserved3 (rserved3):** reserved
0	0b RW	**Timer Overflow Status (TMROF_STS) (tmrof_sts):** This is the timer overflow status bit. This bit gets set anytime bit 22 of the 24 bit timer goes low (bits are counted from 0 to 23). This will occur every 2.3435 seconds. See TMROF_EN for the effect when TMROF_STS goes active. Software clears this bit by writing a 1 to it. reset_type=PMU_PLTRST_B

Access Method

Type: I/O Register (Size: 32 bits)

31:24	0b RO	**reserved:** Reserved.
23:0	0b RO	**Timer Value (TMR_VAL) (tmr_val):** This read-only field returns the running count of the PM timer. This counter runs off a 3.579545 MHz clock (derived from 14.31818 MHz divided by 4). It is reset (to 0) during a Platform reset, and then continues counting as long as the system is in the S0 state. Anytime bit 22 of the timer goes HIGH to LOW (bits referenced from 0 to 23), the TMROF_STS bit is set. The High-to-Low transition will occur every 2.3435 seconds. Writes to this register have no effect.

3.57.4 GPE0a_STS - General Purpose Event 0 Status (GPE0a_STS)—Offset 20h

Note: This register is symmetrical to the General Purpose Event 0a Enable Register. Unless indicated otherwise below, if the corresponding _EN bit is set, then when the STS bit get set, the PMC will generate a Wake Event. Once back in an S0 state (or if already in an S0 state when the event occurs), the PMC will also generate an SCI if the SCI_EN bit is set, or an SMI# if the SCI_EN bit is not set. CLARIFICATION: Bits 15:0 should not be reset by CF9 write. Bits 31:16 are reset by CF9h full resets. reset_type=RSMRST_B

13	0b RW	**Power Management Event Bus 0 Status (PME_B0_STS) (pme_b0_sts):** This bit will be set to 1 by the PMC when any internal device with PCI Power Management capabilities on bus 0 asserts the equivalent of the PME# signal. Additionally, if the PME_B0_EN and SCI_EN bits are set, and the system is in an S0 state, then the setting of the PME_B0_STS bit will generate an SCI (or SMI# if SCI_EN is not set). This bit is cleared by a software write of '1'. Internal devices which can set this bit: - Integrated LAN - HD Audio - SATA - USB
12:11	0b RO	**reserved (reserved3):** Reserved.
10	0b RW	**Battery Low Status (BATLOW_STS) (batlow_sts):** This bit will be set to 1 by hardware when the PMU_BATLOW_B signal goes low. Software clears the bit by writing a 1 to the bit position. In Desktop Mode, this bit will be treated as Reserved.
9	0b RW	**PCI Express Status (PCI_EXP_STS) (pci_exp_sts):** This bit will be set to 1 by hardware to indicate that: - The PME event message was received on one or more of the PCI-Express Ports Note: The PCI PMU_WAKE_B pin and the PCI-Express Beacons have no impact on this bit. Software attempts to clear this bit by writing a 1 to this bit position. If the bit is not cleared and the corresponding PCI_EXP_EN bit is set, the leveltriggered SCI will remain active. Note that a race condition exists where the PCI Express device sends another PME message because the PCI Express device was not serviced within the time when it must resend the message. This may result in a spurious interrupt, and this is comprehended and approved by the PCI Express specification. The window for this race condition is approximately 95-105 milliseconds.
8	0b RW	**PCI Express Wake3 Status (PCIE_WAKE3_STS) (pcie_wake3_sts):** This bit is set by hardware to indicate that the PCI_WAKE3_B pin was asserted. Software writes a 1 to clear this bit. If PCI_WAKE3_B pin is still active during the write, then the bit will remain active (i.e. input to this bit is level sensitive). reset_type=pmc_global_rst_b
7	0b RW	**PCI Express Wake2 Status (PCIE_WAKE2_STS) (pcie_wake2_sts):** This bit is set by hardware to indicate that the PCI_WAKE2_B pin was asserted. Software writes a 1 to clear this bit. 2	0b RW	**Software GPE Status (SWGPE_STS) (swgpe_sts):** The SWGPE_CTRL bit (bit 1 of GPE_CTRL reg) acts as a level input to this bit.
1	0b RO	**Hot Plug Status (HOT_PLUG_STS) (hot_plug_sts):** This bit is set to 1 by hardware when a PCI-Express hot plug event occurs. This will cause an SCI if the HOT_PLUG_EN and SCI_EN bits are set. This bit is cleared by writing a 1 to this bit position. The following events cause this bit to set - Assert_GPE message received from any of the PCI_E ports in the SOC - Assert_HPGPE message received from any of the PCI_E ports in the SOC

31:19	0b RO	**reserved:** Reserved.
18	0b RW	**Intel USB 2 Enable (USB_IS_SMI_EN): (usb_is_smi_en):** Enables Intel-Specific USB2 SMI logic to cause SMI#.
17	0b RW	**USB SMI Enable (USB_SMI_EN): (usb_smi_en):** Enables SMI from USB
16:15	0b RO	**reserved1:** Reserved.
14	0b RW	**Periodic Enable (PERIODIC_EN) (periodic_en):** Setting this bit will cause the PMC to generate an SMI# when the PERIODIC_STS bit is set in the SMI_STS register.
13	0b RW	**TCO Enable (TCO_EN): (tco_en):** when set Enables the TCO logic to generate SMI#. when cleared disables TCO logic generating an SMI#. NOTE: This bit can not be written once the TCO_LOCK bit is set. This prevents unauthorized software from disabling the generation of TCO-based SMI's
12:8	0b RO	**reserved2:** Reserved.
7	0b RW	**BIOS_RLS (BIOS_RLS): (bios_rls):** Enables the generation of an SCI interrupt for ACPI software when a one is written to this bit position by BIOS software. This bit always reads a zero. NOTE: GBL_STS being set will cause an SCI, even if the SCI_EN bit is not set. Software must take great care not to set the BIOS_RLS bit (which causes GBL_STS to be set) if the SCI handler is not in place.
6	0b RW	**Software SMI Timer Enable (SWSMI_TMR_EN): (swsmi_tmr_en):** Software sets this bit to a 1 to start the Software SMI# Timer. When the timer expires (depending on the SWSMI_RATE_SEL bits), it will generate an SMI# and set the SWSMI_TMR_STS bit. The SWSMI_TMR_EN bit will remain at 1 until software sets it back to 0. Clearing the SWSMI_TMR_EN bit before the timer expires will reset the timer and the SMI# will not be generated. The default for this bit is 0.
5	0b RW	**APMC_EN (apmc_en):** APMC Enable - If set, this enables writes to the APM register to cause an SMI#

Bit Range	Default & Access	Description
4	0b RW	**SMI On Sleep Enable (SMI_ON_SLP_EN): (smi_on_slp_en):** If this bit is set, the PMC will generate an SMI# when a write access attempts to set the SLP_EN bit (in the PM1_CNT register). Furthermore, the PMC will not put the system to a sleep state. This allows the SMI# handler work around chip-level bugs. It is expected that the SMI# handler will turn off the SMI_ON_SLP_EN bit before actually setting the SLP_EN bit.
3	0b RO	**reserved4:** Reserved.
2	0b RW	**BIOS Enable (BIOS_EN): (bios_en):** Enables the generation of SMI# when ACPI software writes a 1 to the GBL_RLS bit. Note that if the BIOS_STS bit, which gets set when software writes a 1 to GBL_RLS bit, is already a 1 at the time that BIOS_EN becomes 1, an SMI# will be generated when BIOS_EN gets set.
1	1b RW	**End of SMI (EOS): (eos):** SMI handler sets this bit when it finishes handling the SMI. Setting this bit will force the PMC internal SMI request to zero for 1 clock.Thus if the internal SMI request is still asserted due to new SMI trigger a new rising edge will happen, setting the interrupt to the PMC controller.
0	0b RW	**Global SMI Enable (GBL_SMI_EN): (gbl_smi_en):** When set, this bit enables the generation of SMIs in the system upon any enabled SMI event. This bit is reset by a PMU_PLTRST_B reset event. If this bit is not set, no SMI# will be generated. NOTE: When the SMI_LOCK bit is set, this bit cannot be changed.

ACPI_BASE_ADDRESS Type: PCI Configuration Register (Size: 32 bits)
ACPI_BASE_ADDRESS Reference: [B:0, D:31, F:0] + 40h

Bit Range	Default & Access	Description
31:18	0b RO	**reserved (reserved2):** Reserved.
17	0b RW	**Second Timeout Status(SECOND_TO_STS) (second_to_sts):** PMC sets this bit to 1 to indicate that the TIMEOUT bit had been (or is currently) set and a second timeout occurred before the TCO_RLD register was written. If this bit is set and the NO_REBOOT config bit is 0, then the PMC will reboot the system after the second timeout. The reboot is done by asserting PMU_PLTRST_B. This bit is only cleared by writing a 1 to this bit or by a RSMRST_B.
16:4	0b RO	**reserved (reserved1):** Reserved.

Bit Range	Default & Access	Description

19:13	0b RO	**reserved (reserved2):** Reserved.
12	0b RW	**TCO Lock (TCO_LOCK) (tco_lock):** When set to 1, this bit prevents writes from changing the TCO_EN bit (in offset 30h of Power Management I/O space). Once this bit is set to 1, it can not be cleared by software writing a 0 to this bit location. A core-well reset is required to change this bit from 1 to 0. This bit defaults to 0.
11	0b RW	**TCO Timer Halt (TCO_TMR_HALT) (tco_tmr_halt):** 1 = The TCO timer will halt. It will not count, and thus cannot reach a value that would cause an SMI# or to cause the SECOND_TO_STS bit to be set. This will also prevent rebooting. 0 = The TCO timer is enabled to count. This is the default.

Values of 0000h or 0001h will be ignored and should not be attempted. The timer is clocked at approximately 0.6 seconds, and thus allows timeouts ranging from 1.2 second to 613.8 seconds. Note: The timer has an error of +/- 1 tick (0.6s). The TCO Timer will only count down in the S0 state.

3.58.2 HSFSTS (Hardware_Sequencing_Flash_Status_bios)—Offset 4h

Hardware sequencing flash status Note: If operating in Non-Descriptor mode, the Software Sequencing Flash Status register must be used.

Access Method

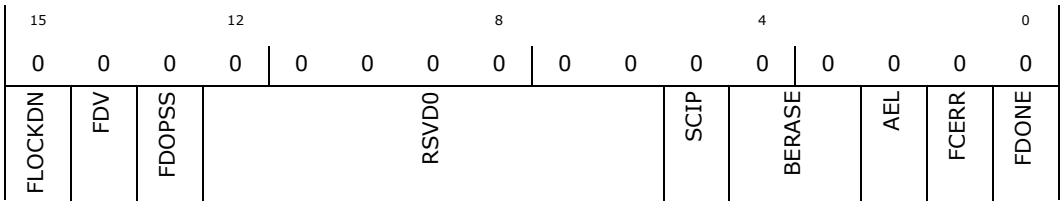
Type: Memory Mapped I/O Register (Size: 16 bits)

Hardware_Sequencing_Flash_Status_bios: [SPI_BASE_ADDRESS] + 4h

SPI_BASE_ADDRESS Type: PCI Configuration Register (Size: 32 bits)

SPI_BASE_ADDRESS Reference: [B:0, D:31, F:0] + 54h

Default: 0000h



Bit Range	Default & Access	Description
15	0b RW/L	**Flash Configuration Lock-Down (FLOCKDN):** When set to 1, those Flash Program Registers that are locked down by this FLOCKDN bit cannot be written. Once set to 1, this bit can only be cleared by a hardware reset.
14	0b RO	**Flash Descriptor Valid (FDV):** This bit is set to a 1 if the Flash Controller read the correct Flash Descriptor Signature. If the Flash Descriptor Valid bit is not 1 , software cannot use the Hardware Sequencing registers, but must use the software sequencing registers. Any attempt to use the Hardware Sequencing registers will result in the FCERR bit being set.
13	0b RO	**Flash Descriptor Override Pin-Strap Status (FDOPSS):** This register reflects the value the Flash Descriptor Override Pin-Strap. '1': No override '0': The Flash Descriptor Override strap is set
12:6	0b RO	**RSVD0:** Reserved

Bit Range	Default & Access	Description
5	0b RO	**SPI Cycle In Progress (SCIP):** Hardware sets this bit when software sets the Flash Cycle Go (FGO) bit in the Hardware Sequencing Flash Control register. This bit remains set until the cycle completes on the SPI interface. Hardware automatically sets and clears this bit so that software can determine when read data is valid and/or when it is safe to begin programming the next command. Software must only program the next command when this bit is 0.
4:3	00b RO	**Block/Sector Erase Size (BERASE):** This field identifies the erasable sector size for all Flash components. Valid Bit Settings: 00 : 256 Byte 01 : 4K Byte 10 : 8K Byte 11 : 64K Byte If the FLA (FPBA then this field reflects the value in the LVSCC.LBES register. If the FLA)= FPBA then this field reflects the value in the UVSCC.UBES register.
2	0b RW/1C	**Access Error Log (AEL):** Hardware sets this bit to a 1 when a direct read was made by BIOS that violated the security restrictions. Or , when a SB transaction to read/write one of the BIOS registers was accepted with bad SAI - see security table. This bit has no affect on indirect accesses. This bit is cleared by software writing a 1.
1	0b RW/1C	**Flash Cycle Error (FCERR):** Hardware sets this bit to 1 when an program register access is blocked to the FLASH due to one of the protection policies or when any of the programmed cycle registers is written while a programmed access is already in progress. This bit remains asserted until cleared by software writing a 1 or until hardware reset occurs. Software must clear this bit before setting the FLASH Cycle GO bit in this register.
0	0b RW/1C	**Flash Cycle Done (FDONE):** The SPI controller sets this bit to 1 when the SPI Cycle completes after software previously set the FGO bit. This bit remains asserted until cleared by software writing a 1 or hardware reset. When this bit is set and the SPI SMI# Enable bit is set, an internal signal is asserted to the SMI# generation block. Software must make sure this bit is cleared prior to enabling the SPI SMI# assertion for a new programmed access.

3.58.3 HSFCTL (Hardware_Sequencing_Flash_Control_bios)—Offset 6h

Hardware sequencing flash control.

Access Method

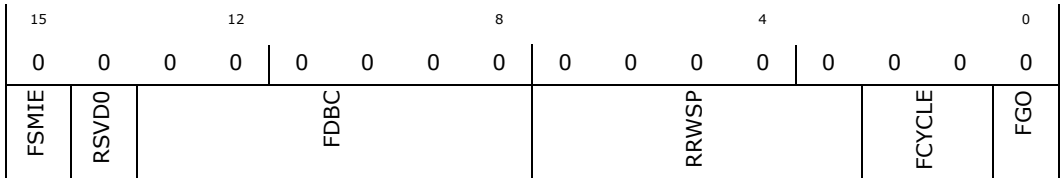
Type: Memory Mapped I/O Register (Size: 16 bits)

Hardware_Sequencing_Flash_Control_bios: [SPI_BASE_ADDRESS] + 6h

SPI_BASE_ADDRESS Type: PCI Configuration Register (Size: 32 bits)

SPI_BASE_ADDRESS Reference: [B:0, D:31, F:0] + 54h

Default: 0000h



Bit Range	Default & Access	Description
15	0b RW	**Flash SPI SMI# Enable (FSMIE):** When set to 1, the SPI asserts an SMI# request whenever the Flash Cycle Done bit is 1.
14	0b RO	**RSVD0:** Reserved
13:8	00h RW	**Flash Data Byte Count (FDBC):** This field specifies the number of bytes to shift in or out during the data portion of the SPI cycle. The contents of this register are 0s based with 0b representing 1 byte and 111111b representing 64 bytes. The number of bytes transferred is the value of this field plus 1. This field is ignored for the Block Erase command.
7:3	00h RW	**Reserved RW Scratch Pad (RRWSP):** Reserved: Scratch Pad bits that are R/W to be used during ECO
2:1	00b RW	**FLASH Cycle (FCYCLE):** This field defines the Flash SPI cycle type generated to the FLASH when the FGO bit is set as defined below: 00 Read (1 up to 64 bytes by setting FDBC) 01 Reserved 10 Write (1 up to 64 bytes by setting FDBC) 11 Block Erase Implementation Note: if reserved 2'b01 is programmed to this field, flash controller will handle it as if it is 00 (Read)
0	0b RW/SE	**Flash Cycle Go (FGO):** A write to this register with a 1 in this bit initiates a request to the Flash SPI Arbiter to start a cycle. This register is cleared by hardware when the cycle is granted by the SPI arbiter to run the cycle on the SPI bus. When the cycle is complete, the FDONE bit is set. Software is forbidden to write to any register in the HSFLCTL register between the FGO bit getting set and the FDONE bit being cleared. Any attempt to violate this rule will be ignored by hardware. Hardware allows other bits in this register to be programmed for the same transaction when writing this bit to 1. This saves an additional memory write. This bit always returns 0 on reads.

3.58.4 FADDR (Flash_Address_bios)—Offset 8h

Flash address

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

Bit Range	Default & Access	Description
31:25	0b RO	**RSVD0:** Reserved

Bit Range	Default & Access	Description
24:0	00000000h RW	**Flash Linear Address (FLA):** The FLA is the starting byte linear address of a SPI Read or Write cycle or an address within a Block for the Block Erase command. The Flash Linear Address must fall within a region for which BIOS has access permissions. Hardware must convert the FLA into a Flash Physical Address (FPA) before running this cycle on the SPI bus. When operating in Tekoa mode bit 24 is ignored and the FLA[lb]13:0[rb] is the FPA.

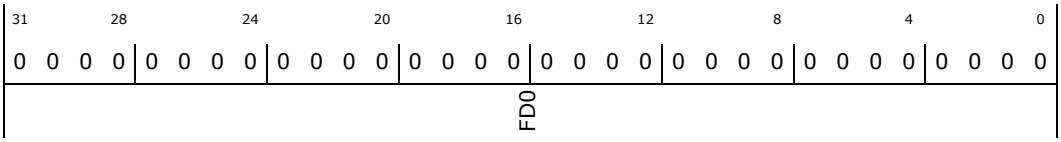
Power Well: EPW

Default: 00000000h



Bit Range	Default & Access	Description
31:0	00000000h RW	**Flash Data 0 (FD0):** This field is shifted out as the SPI Data on the Master-Out Slave-In Data pin during the data portion of the SPI cycle. This register also shifts in the data from the Master-In Slave-Out pin into this register during the data portion of the SPI cycle. The data is always shifted starting with the least significant byte, msb to lsb, followed by the next least significant byte, msb to lsb, etc. Specifically, the shift order on SPI in terms of bits within this register is: 7-6-5-4-3-2-1-0-15-14-13- 8-23-22- 16-31 24 Bit 24 is the last bit shifted out/in. There are no alignment assumptions, byte 0 always represents the value specified by the cycle address. Note that the data in this register may be modified by the hardware during any programmed SPI transaction. Direct Memory Reads do not modify the contents of this register.

This register is locked when the SPI Configuration Lock-Down bit is set or when FREQLOCKDN bit is set.
23	0b RW	**SPI SMI# Enable (SME):** When set to 1, the SPI asserts an SMI# request whenever the Cycle Done Status bit is 1.
22	0b RW	**Data Cycle (DC):** When set to 1, there is data that corresponds to this transaction. When 0, no data is delivered for this cycle, and the DBC and data fields themselves are don t cares.
21:16	000000b RW	**Data Byte Count (DBC):** This field specifies the number of bytes to shift in or out during the data portion of the SPI cycle. The valid settings (in decimal) are any value from 0 to 63. The number of bytes transferred is the value of this field plus 1. Note that when this field is 00_0000b, then there is 1 byte to transfer and that 11_1111b means there are 64 bytes to transfer.
15	0b RO	**RSVD0:** Reserved
14:12	000b RW	**Cycle Opcode Pointer (COP):** This field selects one of the programmed opcodes in the Opcode Menu to be used as the SPI Command/Opcode. In the case of an Atomic Cycle Sequence, this determines the second command.
11	0b RW	**Sequence Prefix Opcode Pointer (SPOP):** This field selects one of the two programmed prefix opcodes for use when performing an Atomic Cycle Sequence. A value of 0 points to the opcode in the least significant byte of the Prefix Opcodes register. By making this programmable, the SPI controller supports flash devices that have different opcodes for enabling writes to the data space vs. status register.
10	0b RW	**Atomic Cycle Sequence (ACS):** When set to 1 along with the SCGO assertion, the SPI controller will execute a sequence of commands on the SPI interface without allowing the LAN component to arbitrate and interleave cycles. The sequence is composed of:) Atomic Sequence Prefix Command (8-bit opcode only)) Primary Command specified below by software (can include address and data)) Polling the Flash Status Register (opcode 8'h05) until bit 0 becomes 1'b0. The SPI Cycle in Progress bit remains set and the Cycle Done Status bit remains unset until the Busy bit in the Flash Status Register returns 0.
9	0b RW/SE	**SPI Cycle Go (SCGO):** This bit always returns 1'b0 on reads. However, a write to this register with a 1'b1 in this bit starts the SPI cycle defined by the other bits of this register. The SPI Cycle in Progress (SCIP) bit gets set by this action. Hardware must ignore writes to this bit while the Cycle In Progress bit is set. Hardware allows other bits in this register to be programmed for the same transaction when writing this bit to 1'b1. This saves an additional memory write.
8	0b RO	**RSVD1:** Reserved

Bit Range	Default & Access	Description

5	0b RO	**RSVD2:** Reserved
4	0b RO	**Access Error Log (AEL):** This bit reflects the value of the Hardware Sequencing Status.AEL register.
3	0b RW/1C	**Flash Cycle Error (FCERR):** Hardware sets this bit to 1'b1 when a programmed access is blocked from running on the SPI interface due to one of the protection policies or when any of the programmed cycle registers is written while a programmed access is already in progress. This bit remains asserted until cleared by software writing a 1'b1 or hardware reset.
2	0b RW/1C	**Cycle Done Status (CDS):** The SPI controller sets this bit to 1'b1 when the SPI Cycle completes i.e., SCIP bit is 1'b0) after software sets the GO bit. This bit remains asserted until cleared by software writing a 1'b1 or hardware reset. When this bit is set and the SPI SMI# Enable bit is set, an internal signal is asserted to the SMI# generation block. Software must make sure this bit is cleared prior to enabling the SPI SMI# assertion for a new programmed access.
1	0b RO	**RSVD3:** Reserved
0	0b RO	**SPI Cycle In Progress (SCIP):** Hardware sets this bit when software sets the SPI Cycle Go bit in the Command register. This bit remains set until the cycle completes on the SPI interface. Hardware automatically sets and clears this bit so that software can determine when read data is valid and/or when it is safe to begin programming the next command. Software must only program the next command when this bit is 1'b0.

The hardware implementation also uses the read vs. write information for modifying the behavior of the SPI interface logic. The encoding of the two bits is: 00 = No Address associated with this Opcode and Read Cycle type 01 = No Address associated with this Opcode and Write Cycle type 10 = Address required, Read cycle type 11 = Address required, Write cycle type

3.58.35 OPMENU0 (Opcode_Menu_Configuration_0_bios)—Offset 98h

Opcode (0-3) Menu Configuration. This register is not writable when the SPI Configuration Lock-Down bit is set or when OPMENULOCKDN bit is set. Four entries are available in this register and four are available in OPMENU1 register to give BIOS a sufficient set of commands for communicating with the flash device, while also restricting what malicious software can do. This keeps the hardware flexible enough to operate with a wide variety of SPI devices. It is recommended that BIOS avoid programming Write Enable opcodes in this menu. Malicious software could then perform writes and erases to the SPI flash without using the atomic cycle mechanism. This could cause functional failures in a shared flash environment. Write Enable opcodes should only be programmed in the Prefix Opcodes.

If this bit [lb]5[rb] is clear, then BIOS is writable based only on WPD = 1'b1 and the iosfep_xxx_hprot[lb]1[rb] signal is a don't care.
4	0b RO	**RSVD1:** Reserved
3:2	00b RW	**SPI Read Configuration (SRC):** This 2-bit field controls two policies related to BIOS reads on the SPI interface: Bit 3 - Prefetch Enable, Bit 2 - Cache Disable. Settings are summarized below: '00' : No prefetching, but caching enabled. Direct Memory reads load the read buffer cache with 'valid' data, allowing repeated reads to the same range to complete quickly. '01' : No prefetching and no caching. One-to-one correspondence of host BIOS reads to SPI cycles. This value can be used to invalidate the cache. '10' : Prefetching and Caching enabled. This mode is used for long sequences of short reads to consecutive addresses (i.e. shadowing) '11' : Illegal. Caching must be enabled when Prefetching is enabled. This eliminates the need for a complex prefetch-flushing mechanism. Note that if BIOS direct read caching is disabled while data has already been cached internally, subsequent BIOS direct reads will continue to return data from the cache until the cache is invalidated.
1	0b RW/L	**Lock Enable (LE):** When set, WPD bit could be set from a 1'b0 to a 1'b1 only by SMM code. When cleared, setting the WP bit is allowed in all modes and SMI is not generated. Once set, this bit can only be cleared by a PLTRST#. When this bit is set, EISS - bit [lb]5[rb] of this register is locked down.
0	0b RW	**Write Protect Disable (WPD):** When set, access to the BIOS space is enabled for both read and write cycles. When cleared, only read cycles are permitted to the flash. When LE bit is set this bit could be written from a 1'b0 to a 1'b1 only by SMM code. When not SMM code tries to writes this bit from a 1'b0 to a 1'b1, bit remain in its 1'b0 value. An Async-SMI is generated (Send ASSERT_SMI) if SMIWPEN is set. This ensures that only SMM code can update BIOS.

3.59.1 Receiver Buffer / Transmitter Holding Register (COM1_Rx_Tx_Buffer)—Offset 3F8h

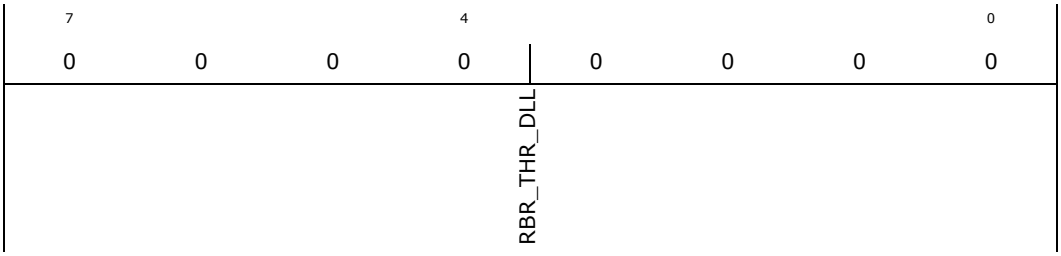
This register is a combination of three registers: the receiver buffer register (RBR) that is a read-only register when DLAB=0, the transmitter holding register (THR) that is a write-only register when DLAB=0 and the divisor latch LSB (DLL) register when DLAB=1.

Access Method

Type: I/O Register
(Size: 8 bits)

COM1_Rx_Tx_Buffer: 3F8h

Default: 00h



Bit Range	Default & Access	Description
7:0	00h RW	**Receiver buffer / transmitter holding (RBR_THR_DLL): When reading from this register and DLAB=1'b0**, it contains the byte received if no FIFO is used, or the oldest unread byte with FIFO's. If FIFO buffering is used, each new read action of the register will return the next byte, until no more bytes are present. Bit 0 in the LSR line status register can be used to check if all received bytes have been read. This bit will change to zero if no more bytes are present. **When writing to this register and DLAB=1'b0**, it is used to buffer outgoing characters. If no FIFO buffering is used, only one character can be stored. Otherwise the amount of characters depends on the type of UART. Bit 5 in the LSR, line status register can be used to check if new information must be written to this register. The value 1'b1 indicates that the register is empty. If FIFO buffering is used, more than one character can be written to the transmitter holding register when the bit signals an empty state. There is no indication of the amount of bytes currently present in the transmitter FIFO. This register is not used to transfer the data directly. The byte is first transferred to a shift register where the information is broken in single bits which are sent one by one. **If DLAB=1'b1**, this register is used as DLL (Divisor Latch LSB). For generating its timing information, each UART uses an oscillator generating a frequency of about 1.8432 MHz. This frequency is divided by 16 to generate the time base for communication. Because of this division, the maximum allowed communication speed is 115200 bps. Modern UARTS like the 16550 are capable of handling higher input frequencies up to 24 MHz which makes it possible to communicate with a maximum speed of 1.5 Mbps. On PC's higher frequencies than the 1.8432 MHz are rarely seen because this would be software incompatible with the original XT configuration. This 115200 bps communication speed is not suitable for all applications. To change the communication speed, the frequency can be further decreased by dividing it by a programmable value. For very slow communications, this value can go beyond 255. Therefore, the divisor is stored in two separate bytes, the divisor latch registers DLL and DLM which contain the least, and most significant byte. For error free communication, it is necessary that both the transmitting and receiving UART use the same time base. Default values have been defined which are commonly used. The table shows the most common values with the appropriate settings of the divisor latch bytes. Note that these values only hold for a PC compatible system where a clock frequency of 1.8432 MHz is used. Speed(bps) Divisor DLL DLM 50 2,304 0x00 0x09 300 384 0x80 0x01 1,200 96 0x60 0x00 2,400 48 0x30 0x00 4,800 24 0x18 0x00 9,600 12 0x0C 0x00 19,200 6 0x06 0x00 38,400 3 0x03 0x00 57,600 2 0x02 0x00 115,200 1 0x01 0x00

Bit Range	Default & Access	Description
7:0	00h RW	**Interrupt Enable (IER_DLM): If DLAB=1'b0**, This field is used as interrupt enable register. The smartest way to perform serial communications on a PC is using interrupt driven routines. In that configuration, it is not necessary to poll the registers of the UART periodically for state changes. The UART will signal each change by generating a processor interrupt. A software routine must be present to handle the interrupt and to check what state change was responsible for it. Interrupts are not generated, unless the UART is told to do so. This is done by setting bits in the IER, interrupt enable register. A bit value 1 indicates, that an interrupt may take place. Bit Description 0 ERBFI - Enable Received Data Available Interrupt. This is used to enable/disable the generation of Received Data Available Interrupt and the Character Timeout Interrupt (if in FIFO mode and FIFOs enabled). These are the second highest priority interrupts. 1 ETBEI - Enable Transmit Holding Register Empty Interrupt. This is used to enable/disable the generation of Transmitter Holding Register Empty Interrupt. This is the third highest priority interrupt. 2 ELSI - Enable Receiver Line Status Interrupt. This is used to enable/disable the generation of Receiver Line Status Interrupt. This is the highest priority interrupt. 3 EDSSI - Enable Modem Status Interrupt. This is used to enable/disable the generation of Modem Status Interrupt. This is the fourth highest priority interrupt. 4 Reserved and read as zero 5 Reserved and read as zero 6 Reserved and read as zero 7 PTIME - Programmable THRE Interrupt Mode Enable that can be written to only when THRE_MODE_USER == Enabled, always readable. This is used to enable/disable the generation of THRE Interrupt. **If DLAB=1'b1**, this register is used as DLM (Divisor Latch MSB). See DLL field description in the Rx_Tx_Buffer register.

3.59.3 Interrupt Identification / FIFO Control Register (COM1_IIR)—Offset 3FAh

This register is a combination of two registers: the interrupt identification register (IIR) that is a read-only register and the FIFO control register (FCR) that is a write-only register. If FIFOs are not implemented, the FIFO control register does not exist and writing to this register address has no effect.

'00' - disabled '11' - enabled **Write** to this field is used to select the trigger level in the receiver FIFO at which the Received Data Available Interrupt is generated. In auto flow control mode it is used to determine when the rts_n signal is de-asserted. The following trigger levels are supported: '00' - 1 character in the FIFO '01' - FIFO 1/4 full '10' - FIFO 1/2 full '11' - FIFO 2 less than full

The following trigger levels are supported: '00' - FIFO empty '01' - 2 characters in the FIFO '10' - FIFO 1/4 full '11' - FIFO 1/2 full
3:0	0001b RO	**Interrupt ID (IIR): Read** from this field indicates the highest priority pending interrupt which can be one of the following types: '0000' - modem status '0001' - no interrupt pending '0010' - THR empty '0100' - received data available '0110' - receiver line status '0111' - busy detect '1100' - character timeout **Write** to this field is split to four bits: Bit Description 3 DMA Mode, determines the DMA signalling mode used: '0'- mode 0, '1' - mode 1 2 XMIT FIFO Reset, resets the control portion of the transmit FIFO and treats the FIFO as empty. 1 RCVR FIFO Reset, resets the control portion of the receive FIFO and treats the FIFO as empty. 0 FIFO Enable. This enables/disables the transmit (XMIT) and receive (RCVR) FIFOs. Whenever the value of this bit is changed both the XMIT and RCVR controller portion of FIFOs is reset.

3.59.4 Line Control Register (COM1_LCR)—Offset 3FBh

The LCR, line control register is used at initialization to set the communication parameters. Parity and number of data bits can be changed for example. The register also controls the accessibility of the DLL and DLM registers. These registers are mapped to the same I/O port as the RBR, THR and IER registers. Because they are only accessed at initialization when no communication occurs this register swapping has no influence on performance.

Access Method

Type: I/O Register

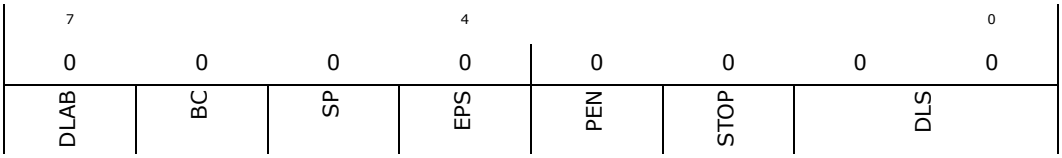
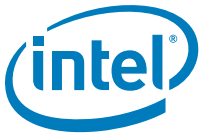
COM1_LCR: 3FBh

Default: 00h





Bit Range	Default & Access	Description
7	0b RW	**Divisor Latch Access Bit (DLAB):** This field is used to enable reading and writing of the Divisor Latch register (DLL and DLH) to set the baud rate of the UART. This bit must be cleared after initial baud rate setup in order to access other registers. '0' - RBR, THR and IER accessible '1' - DLL and DLM accessible See Rx_Tx_Buffer and IER registers description for more details.
6	0b RW	**Break Control (BC):** This is used to cause a break condition to be transmitted to the receiving device. If set to one the serial output is forced to the spacing (logic 0) state. When not in Loopback Mode, as determined by MCR[4], the sout line is forced low until the Break bit is cleared. If SIR_MODE == Enabled and active (MCR[6] set to one) the sir_out_n line is continuously pulsed. When in Loopback Mode, the break condition is internally looped back to the receiver and the sir_out_n line is forced low.
5	0b RO	**Stick Parity (SP):** Reserved and read as zero
4	0b RW	**Even Parity Select (EPS):** This is used to select between even and odd parity, when parity is enabled (PEN set to one). If set to one, an even number of logic 1s is transmitted or checked. If set to zero, an odd number of logic 1s is transmitted or checked.
3	0b RW	**Parity Enable (PEN):** This is used to enable and disable parity generation and detection in transmitted and received serial character respectively. '0' - parity disabled '1' - parity enabled
2	0b RW	**Number ofStop bits (STOP):** This is used to select the number of stop bits per character that the peripheral transmits and receives. If set to zero, one stop bit is transmitted in the serial data. If set to one and the data bits are set to 5 (LCR[1:0] set to zero) one and a half stop bits is transmitted. Otherwise, two stop bits are transmitted. Note that regardless of the number of stop bits selected, the receiver checks only the first stop bit. '0' - 1 stop bit '1' - 1.5 stop bits when DLS (LCR[1:0]) is zero, else 2 stop bit
1:0	00b RW	**Data Length Select (DLS):** This is used to select the number of data bits per character that the peripheral transmits and receives. The number of bit that may be selected areas follows: '00' - 5 bits '01' - 6 bits '10' - 7 bits '11' - 8 bits

3.59.5 Modem Control Register (COM1_MCR)—Offset 3FCh

The MCR, modem control register is used to perform handshaking actions with the attached device. In the original UART series including the 16550, setting and resetting of the control signals must be done by software. The new 16750 is capable of handling flow control automatically, thereby reducing the load on the processor.

RSVD0	SIRE	AFCE	LB	OUT2	OUT1	RTS	DTR

Bit Range	Default & Access	Description
7	0b RO	**RSVD0:** Reserved
6	0b RW	**SIR Mode Enable (SIRE):** Writeable only when SIR_MODE == Enabled, always readable. This is used to enable/disable the IrDA SIR Mode features as described in 'IrDA 1.0 SIR Protocol' on Synopsys UART specification. '0' - IrDA SIR Mode disabled '1' - IrDA SIR Mode enabled
5	0b RW	**Auto Flow Control Enable (AFCE):** Writeable only when AFCE_MODE == Enabled, always readable. When FIFOs are enabled and the Auto Flow Control Enable (AFCE) bit is set, Auto Flow Control features are enabled as described in 'Auto Flow Control' on Synopsys UART specification. '0' - Auto Flow Control Mode disabled '1' - Auto Flow Control Mode enabled
4	0b RW	**LoopBack (LB):** This is used to put the UART into a diagnostic mode for test purposes. If operating in UART mode (SIR_MODE != Enabled or not active, MCR[6] set to zero), data on the sout line is held high, while serial data output is looped back to the sin line, internally. In this mode all the interrupts are fully functional. Also, in loopback mode, the modem control inputs (dsr_n, cts_n, ri_n, dcd_n) are disconnected and the modem control outputs (dtr_n, rts_n, out1_n, out2_n) are looped back to the inputs, internally. If operating in infrared mode (SIR_MODE == Enabled AND active, MCR[6] set to one), data on the sir_out_n line is held low, while serial data output is inverted and looped back to the sir_in line.
3	0b RW	**Auxiliary output 2 (OUT2):** This is used to directly control the user-designated Output2 (out2_n) output. The value written to this location is inverted and driven out on out2_n, that is: '0' - out2_n de-asserted (logic 1) '1' - out2_n asserted (logic 0) Note that in Loopback mode (MCR[4] set to one), the out2_n output is held inactive high while the value of this location is internally looped back to an input.
2	0b RW	**Auxiliary output 1 (OUT1):** This is used to directly control the user-designated Output1 (out1_n) output. The value written to this location is inverted and driven out on out1_n, that is: '0' - out1_n de-asserted (logic 1) '1' - out1_n asserted (logic 0) Note that in Loopback mode (MCR[4] set to one), the out1_n output is held inactive high while the value of this location is internally looped back to an input.

Bit Range	Default & Access	Description
1	0b RW	**Request to Send (RTS):** This is used to directly control the Request to Send (rts_n) output. The Request To Send (rts_n) output is used to inform the modem or data set that the UART is ready to exchange data. When Auto RTS Flow Control is not enabled (MCR[5] set to zero), the rts_n signal is set low by programming MCR[1] (RTS) to a high.In Auto Flow Control, AFCE_MODE == Enabled and active (MCR[5] set to one) and FIFOs enable (FCR[0] set to one), the rts_n output is controlled in the same way, but is also gated with the receiver FIFO threshold trigger (rts_n is inactive high when above the threshold). The rts_n signal is de-asserted when MCR[1] is set low. Note that in Loopback mode (MCR[4] set to one), the rts_n output is held inactive high while the value of this location is internally looped back to an input. Note that PCU-UART does not implement the Request to Send (rts_n) output.
0	0b RW	**Data Terminal Ready (DTR):** This is used to directly control the Data Terminal Ready (dtr_n) output. The value written to this location is inverted and driven out on dtr_n, that is: '0' - dtr_n de-asserted (logic 1) '1' - dtr_n asserted (logic 0) The Data Terminal Ready output is used to inform the modem or data set that the UART is ready to establish communications. Note that in Loopback mode (MCR[4] set to one), the dtr_n output is held inactive high while the value of this location is internally looped back to an input. Note that PCU-UART does not implement the Data Terminal Ready (dtr_n) output.

RFE	TEMT	THRE	BI	FE	PE	OE	DR

Bit Range	Default & Access	Description
7	0b RO	**Receiver FIFO Error (RFE):** This bit is only relevant when FIFO_MODE != NONE AND FIFOs are enabled (FCR[0] set to one). This is used to indicate if there is at least one parity error, framing error, or break indication in the FIFO. '0' - no error in RX FIFO '1' - error in RX FIFO This bit is cleared when the LSR is read and the character with the error is at the top of the receiver FIFO and there are no subsequent errors in the FIFO.

Bit Range	Default & Access	Description
6	1b RO	**Transmitter Empty (TEMT):** If in FIFO mode (FIFO_MODE != NONE) and FIFOs enabled (FCR[0] set to one), this bit is set whenever the Transmitter Shift Register and the FIFO are both empty. If in non-FIFO mode or FIFOs are disabled, this bit is set whenever the Transmitter Holding Register and the Transmitter Shift Register are both empty.
5	1b RO	**Transmit Holding Register Empty (THRE):** If THRE_MODE_USER == Disabled or THRE mode is disabled (IER[7] set to zero) and regardless of FIFO's being implemented/enabled or not, this bit indicates that the THR or TX FIFO is empty. This bit is set whenever data is transferred from the THR or TX FIFO to the transmitter shift register and no new data has been written to the THR or TX FIFO. This also causes a THRE Interrupt to occur, if the THRE Interrupt is enabled. If THRE_MODE_USER == Enabled AND FIFO_MODE != NONE and both modes are active (IER[7] set to one and FCR[0] set to one respectively), the functionality is switched to indicate the transmitter FIFO is full, and no longer controls THRE interrupts, which are then controlled by the FCR[5:4] threshold setting.
4	0b RO	**Break Interrupt (BI):** This is used to indicate the detection of a break sequence on the serial input data. If in UART mode (SIR_MODE == Disabled), it is set whenever the serial input, sin, is held in a logic '0' state for longer than the sum of start time + data bits + parity + stop bits. If in infrared mode (SIR_MODE == Enabled), it is set whenever the serial input, sir_in, is continuously pulsed to logic '0' for longer than the sum of start time + data bits + parity + stop bits. A break condition on serial input causes one and only one character, consisting of all zeros, to be received by the UART. In the FIFO mode, the character associated with the break condition is carried through the FIFO and is revealed when the character is at the top of the FIFO. Reading the LSR clears the BI bit. In the non-FIFO mode, the BI indication occurs immediately and persists until the LSR is read.
3	0b RO	**Framing Error (FE):** This is used to indicate the occurrence of a framing error in the receiver. A framing error occurs when the receiver does not detect a valid STOP bit in the received data. In the FIFO mode, since the framing error is associated with a character received, it is revealed when the character with the framing error is at the top of the FIFO. When a framing error occurs, the UART tries to resynchronize. It does this by assuming that the error was due to the start bit of the next character and then continues receiving the other bit i.e. data, and/or parity and stop. It should be noted that the Framing Error (FE) bit (LSR[3]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). '0' - no framing error '1' - framing error Reading the LSR clears the FE bit.
2	0b RO	**Parity Error (PE):** This is used to indicate the occurrence of a parity error in the receiver if the Parity Enable (PEN) bit (LCR[3]) is set. In the FIFO mode, since the parity error is associated with a character received, it is revealed when the character with the parity error arrives at the top of the FIFO. It should be noted that the Parity Error (PE) bit (LSR[2]) is set if a break interrupt has occurred, as indicated by Break Interrupt (BI) bit (LSR[4]). '0' - no parity error '1' - parity error Reading the LSR clears the PE bit.

Bit Range	Default & Access	Description
1	0b RO	**Overrun Error (OE):** This is used to indicate the occurrence of an overrun error. This occurs if a new data character was received before the previous data was read. In the non-FIFO mode, the OE bit is set when a new character arrives in the receiver before the previous character was read from the RBR. When this happens, the data in the RBR is overwritten. In the FIFO mode, an overrun error occurs when the FIFO is full and a new character arrives at the receiver. The data in the FIFO is retained and the data in the receive shift register is lost. '0' - no overrun error '1' - overrun error Reading the LSR clears the OE bit.
0	0b RO	**Data Ready (DR):** This is used to indicate that the receiver contains at least one character in the RBR or the receiver FIFO. '0' - no data ready '1' - data ready This bit is cleared when the RBR is read in non-FIFO mode, or when the receiver FIFO is empty, in FIFO mode.

3.59.7 Modem Status Register (COM1_MSR)—Offset 3FEh

The MSR, modem status register contains information about the four incoming modem control lines on the device. The information is split in two nibbles. The four most significant bits contain information about the current state of the inputs where the least significant bits are used to indicate state changes. The four LSB's are reset, each time the register is read. Whenever bits 0, 1, 2 or 3 are set to logic one, to indicate a change on the modem control inputs, a modem status interrupt is generated if enabled through the IER, regardless of when the change occurred. Since the delta bits (bits 0, 1, 3) can get set after a reset if their respective modem signals are active (see individual bits for details), a read of the MSR after reset can be performed to prevent unwanted interrupts.

7	0b RO	**Data Carrier Detect (DCD):** This is used to indicate the current state of the modem control line dcd_n. This bit is the complement of dcd_n. When the Data Carrier Detect input (dcd_n) is asserted it is an indication that the carrier has been detected by the modem or data set. '0' - dcd_n input is de-asserted (logic 1) '1' - dcd_n input is asserted (logic 0) In Loopback Mode (MCR[4] set to one), DCD is the same as MCR[3] (Out2). Note that PCU-UART does not implement the Data Carrier Detect (dcd_n) input.

Bit Range	Default & Access	Description
6	0b RO	**Ring Indicator (RI):** This is used to indicate the current state of the modem control line ri_n. This bit is the complement of ri_n. When the Ring Indicator input (ri_n) is asserted it is an indication that a telephone ringing signal has been received by the modem or data set. '0' - ri_n input is de-asserted (logic 1) '1' - ri_n input is asserted (logic 0) In Loopback Mode (MCR[4] set to one), RI is the same as MCR[2] (Out1). Note that PCU-UART does not implement the Ring Indicator (ri_n) input.
5	0b RO	**Data Set Ready (DSR):** This is used to indicate the current state of the modem control line dsr_n. This bit is the complement of dsr_n. When the Data Set Ready input (dsr_n) is asserted it is an indication that the modem or data set is ready to establish communications with the DW_apb_uart. '0' - dsr_n input is de-asserted (logic 1) '1' - dsr_n input is asserted (logic 0) In Loopback Mode (MCR[4] set to one), DSR is the same as MCR[0] (DTR). Note that PCU-UART does not implement the Data Set Ready (dsr_n) input.
4	0b RO	**Clear to Send (CTS):** This is used to indicate the current state of the modem control line cts_n. This bit is the complement of cts_n. When the Clear to Send input (cts_n) is asserted it is an indication that the modem or data set is ready to exchange data with the DW_apb_uart. '0' - cts_n input is de-asserted (logic 1) '1' - cts_n input is asserted (logic 0) In Loopback Mode (MCR[4] = 1), CTS is the same as MCR[1] (RTS). Note that PCU-UART does not implement the Clear to Send (cts_n) input.
3	0b RO	**Delta Data Carrier Detect (DDCD):** This is used to indicate that the modem control line dcd_n has changed since the last time the MSR was read. '0' - no change on dcd_n since last read of MSR '1' - change on dcd_n since last read of MSR Reading the MSR clears the DDCD bit. In Loopback Mode (MCR[4] = 1), DDCD reflects changes on MCR[3] (Out2). Note, if the DDCD bit is not set and the dcd_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDCD bit is set when the reset is removed if the dcd_n signal remains asserted. Note that PCU-UART does not implement the Data Carrier Detect (dcd_n) input.
2	0b RO	**Trailing Edge of Ring Indicator (TERI):** This is used to indicate that a change on the input ri_n (from an active-low to an inactive-high state) has occurred since the last time the MSR was read. '0' - no change on ri_n since last read of MSR '1' - change on ri_n since last read of MSR Reading the MSR clears the TERI bit. In Loopback Mode (MCR[4] = 1), TERI reflects when MCR[2] (Out1) has changed state from a high to a low. Note that PCU-UART does not implement the Ring Indicator (ri_n) input.
1	0b RO	**Delta Data Set Ready (DDSR):** This is used to indicate that the modem control line dsr_n has changed since the last time the MSR was read. '0' - no change on dsr_n since last read of MSR '1' - change on dsr_n since last read of MSR Reading the MSR clears the DDSR bit. In Loopback Mode (MCR[4] = 1), DDSR reflects changes on MCR[0] (DTR). Note, if the DDSR bit is not set and the dsr_n signal is asserted (low) and a reset occurs (software or otherwise), then the DDSR bit is set when the reset is removed if the dsr_n signal remains asserted. Note that PCU-UART does not implement the Data Set Ready (dsr_n) input.

Bit Range	Default & Access	Description
0	0b RO	**Delta Clear to Send (DCTS):** This is used to indicate that the modem control line cts_n has changed since the last time the MSR was read. '0' - no change on cts_n since last read of MSR '1' - change on cts_n since last read of MSR Reading the MSR clears the DCTS bit. In Loopback Mode (MCR[4] = 1), DCTS reflects changes on MCR[1] (RTS). Note, if the DCTS bit is not set and the cts_n signal is asserted (low) and a reset occurs (software or otherwise), then the DCTS bit is set when the reset is removed if the cts_n signal remains asserted. Note that PCU-UART does not implement the Clear to Send (cts_n) input.

Bit Range	Default & Access	Description
31:9	0b RO	**RSVD0:** Reserved
8	1b RW	**PFE:** Prefetch Enable (PFE): When set, BIOS prefetching is enabled. An access to BIOS causes a 64-byte fetch of the line starting at that region. Subsequent accesses within that region result in data being returned from the prefetch buffer. The prefetch buffer is invalidated when this bit is cleared, or a BIOS access occurs to a different line than what is currently in the buffer.
7:2	0b RO	**RSVD1:** Reserved
1	0b RW	**LE:** Lock Enable (LE): When set, setting the WP bit will cause SMIs. When cleared, setting the WP bit will not cause SMIs. Once set, this bit can only be cleared by a PMU_PLTRST_B#.
0	0b RW	**WP:** Write Protect (WP): When set, access to BIOS is enabled for both read and write cycles. When cleared, only read cycles are permitted to BIOS. When written from a 0 to a 1 and LE is also set, an SMI# is generated. This ensures that only SMM code can update BIOS.

Access Method

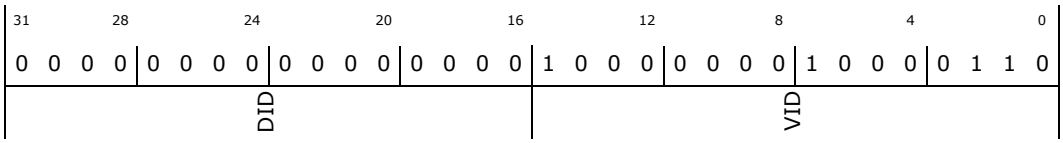
Type: PCI Configuration Register (Size: 32 bits)

PCIE_REG_Identifiers: [B:0, D:31, F:0] + 0h

Default: 00008086h



Bit Range	Default & Access	Description
31:16	X RO	**Device Identification (DID):** This field identifies the particular device. This identifier is allocated by the vendor. This field is controlled by the LPC DID fuses Bits [31:23] are coming from the SETIDVALUE message Device ID[15:7] bits. Bits [22:21] are set constantly to 2'b00. Bits [20:16] are set constantly by pcu_did fuses.
15:0	8086h RO	**Vendor Identification (VID):** This field identifies the manufacturer of the device. Valid vendor identifiers are allocated by the PCI SIG to ensure uniqueness. 0 FFFFh is an invalid value for Vendor ID.

3.61.2 Command (PCIE_REG_COMMAND)—Offset 4h

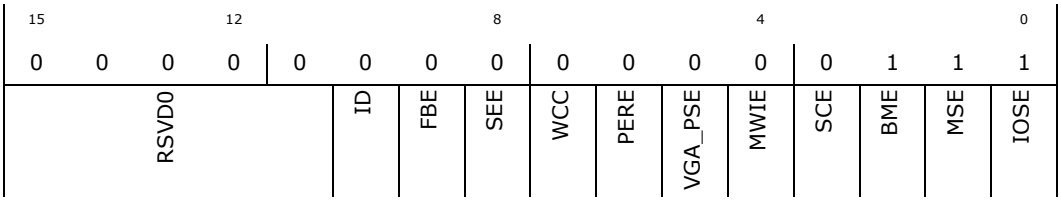
The Command register provides coarse control over a device's ability to generate and respond to PCI cycles. When a 0 is written to this register, the device is logically disconnected from the PCI bus for all accesses except configuration accesses. All devices are required to support this base level of functionality. Individual bits in the Command register may or may not be implemented depending on a device's functionality

Access Method

Type: PCI Configuration Register (Size: 16 bits)

PCIE_REG_COMMAND: [B:0, D:31, F:0] + 4h

Default: 0007h



Bit Range	Default & Access	Description
15:11	0b RO	**RSVD0:** Reserved
10	0b RO	**Interrupt Disable (ID):** This bit disables the device/function from asserting INTx#. A value of 0 enables the assertion of its INTx# signal. A value of 1 disables the assertion of its INTx# signal. The LPC bridge has no interrupts to disable
9	0b RO	**Fast Back to Back Enable (FBE):** This optional read/write bit controls whether or not a master can do fast back-to-back transactions to different devices. A value of 0 means fast back-to-back transactions are only allowed to the same agent
8	0b RW	**SERR# Enable (SEE):** This bit is an enable bit for the SERR# driver. A value of 0 disables the SERR# driver. A value of 1 enables the SERR# driver.
7	0b RO	**Wait Cycle Control (WCC):** Reserved as '0' per PCI-Express spec
6	0b RW	**Parity Error Response Enable (PERE):** This bit controls the device's response to parity errors. When the bit is set, the device must take its normal action when a parity error is detected. When the bit is 0, the device sets its Detected Parity Error status bit (bit 15 in the Status register) when an error is detected, but does not assert PERR# and continues normal operation.
5	0b RO	**VGA Palette Snoop (VGA_PSE):** This bit controls how VGA compatible and graphics devices handle accesses to VGA palette registers. When this bit is 1, palette snooping is enabled (i.e., the device does not respond to palette register writes and snoops the data). When the bit is 0, the device should treat palette write accesses like all other accesses. Reserved as '0' per PCI-Express spec
4	0b RO	**Memory Write and Invalidate Enable (MWIE):** This is an enable bit for using the Memory Write and Invalidate command. When this bit is 1, masters may generate the command. When it is 0, Memory Write must be used instead. Reserved as '0' per PCI-Express spec
3	0b RO	**Special Cycle Enable (SCE):** Controls a device's action on Special Cycle operations. A value of 0 causes the device to ignore all Special Cycle operations. A value of 1 allows the device to monitor Special Cycle operations. Reserved as '0' per PCI-Express spec
2	1b RO	**Bus Master Enable (BME):** Controls a device's ability to act as a master on the PCI bus. A value of 0 disables the device from generating PCI accesses. A value of 1 allows the device to behave as a bus master. Bus master cannot be disabled on LPC
1	1b RO	**Memory Space Enable (MSE):** Controls a device's response to Memory Space accesses. A value of 0 disables the device response. A value of 1 allows the device to respond to Memory Space accesses. Memory space cannot be disable on LPC

Bit Range	Default & Access	Description
0	1b RO	**I/O Space Enable (IOSE):** Controls a device's response to I/O Space accesses. A value of 0 disables the device response. A value of 1 allows the device to respond to I/O Space accesses. I/O space cannot be disable on LPC

3.61.3 Status (PCIE_REG_STATUS)—Offset 6h

The Status register is used to record status information for PCI bus related events. Reads to this register behave normally. Writes are slightly different in that bits can be reset, but not set. A one bit is reset (if it is not read-only) whenever the register is written, and the write data in the corresponding bit location is a 1. For instance, to clear bit 14 and not affect any other bits, write the value 0100_0000_0000_0000b to the register.

Access Method

Type: PCI Configuration Register (Size: 16 bits)

PCIE_REG_STATUS: [B:0, D:31, F:0] + 6h

Default: 0210h

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DPE	SSE	RMA	RTA	STA	DTS		DPD	FBC	RSVD0		C66	CLIST	IS	RSVD1	

Bit Range	Default & Access	Description
15	0b RW	**Detected Parity Error (DPE):** This bit must be set by the device whenever it detects a parity error, even if parity error handling is disabled (as controlled by bit 6 in the Command register).
14	0b RW	**Signaled System Error (SSE):** This bit must be set whenever the device asserts SERR#. Set when the LPC bridge signals a system error to the internal SERR# logic.
13	0b RW	**Received Master Abort (RMA):** This bit must be set by a master device whenever its transaction (except for Special Cycle) is terminated with Master-Abort. All master devices must implement this bit.
12	0b RW	**Received Target Abort: (RTA):** This bit must be set by a master device whenever its transaction is terminated with Target-Abort. All master devices must implement this bit.
11	0b RW	**Signaled Target Abort (STA):** This bit must be set by a target device whenever it terminates a transaction with Target-Abort. Devices that will never signal Target- Abort do not need to implement this bit.
10:9	01b RO	**DEVSEL# Timing Status (DTS):** These bits encode the timing of DEVSEL#. These are encoded as 00b for fast, 01b for medium, and 10b for slow (11b is reserved). These bits Indicate medium timing, although this has no meaning on the backbone

Bit Range	Default & Access	Description
8	0b RW	**Data Parity Error Detected (DPD):** This bit is only implemented by bus masters. It is set when three conditions are met: 1) the bus agent asserted PERR# itself (on a read) or observed PERR# asserted (on a write); 2) the agent setting the bit acted as the bus master for the operation in which the error occurred; and 3) the Parity Error Response bit (Command register) is set.
7	0b RO	**Fast Back to Back Capable (FBC):** This optional read-only bit indicates whether or not the target is capable of accepting fast back-to-back transactions when the transactions are not to the same agent. This bit can be set to 1 if the device can accept these transactions and must be set to 0 otherwise. This bit has no meaning on internal backbone.
6	0b RO	**RSVD0:** Reserved
5	0b RO	**66 MHz Capable (C66):** This optional read-only bit indicates whether or not this device is capable of running at 66 MHz. A value of zero indicates 33 MHz. A value of 1 indicates that the device is 66 MHz capable. This bit has no meaning on internal backbone
4	1b RO	**Capabilities List (CLIST):** This optional read-only bit indicates whether or not this device implements the pointer for a New Capabilities linked list at offset 34h. A value of zero indicates that no New Capabilities linked list is available. A value of one indicates that the value read at offset 34h is a pointer in Configuration Space to a linked list of new capabilities. There is a capabilities list in the LPC bridge.
3	0b RO	**Interrupt Status (IS):** This read-only bit reflects the state of the interrupt in the device/function. Only when the Interrupt Disable bit in the command register is a 0 and this Interrupt Status bit is a 1, will the device's/function's INTx# signal be asserted. Setting the Interrupt Disable bit to a 1 has no effect on the state of this bit. The LPC bridge does not generate interrupts
2:0	0b RO	**RSVD1:** Reserved

3.61.7 Subsystem ID and Vendor ID (PCIE_REG_SUBSYS_VENDOR_ID)—Offset 2Ch

This register is used to uniquely identify the add-in card or subsystem where the PCI device resides. It provides a mechanism for add-in card vendors to distinguish their add- in cards from one another even though the add-in cards may have the same PCI controller on them (and, therefore, the same Vendor ID and Device ID). Implementation of this register is required for all PCI devices except those that have a base class 6 with sub class 0-4 (0, 1, 2, 3, 4), or a base class 8 with sub class 0-3 (0, 1, 2, 3). Subsystem Vendor IDs can be obtained from the PCI SIG and are used to identify the vendor of the add-in card or subsystem. Values for the Subsystem ID are vendor specific. Values in these registers must be loaded and valid prior to the system firmware or any system software accessing the PCI Configuration Space. How these values are loaded is not specified but could be done during the manufacturing process or loaded from external logic (e.g., strapping options, serial ROMs, etc.). These values must not be loaded using expansion ROM software because expansion ROM software is not guaranteed to be run during POST in all systems. Devices are responsible for guaranteeing the data is valid before allowing reads to these registers to complete. This can be done by responding to any accesses with Retry until the data is valid. If a device is designed to be used exclusively on the system board, the system vendor may use system specific software to initialize these registers after each power-on. This register can be written only once after PMU_PLTRST_B de-assertion.

If GPIO(n) is programmed to be an output (via the corresponding bit in the GP_IO_SEL register), then the corresponding GP_LVL(n) write register value will drive a high or low value on the output pin. 1 = high, 0 = low. - Only the 8 lsb are used in VLV
