1 Register Access Methods

Note: Throughout this document Intel® Atom™ Processor Z3600 and Z3700 Series is referred as Processor or SoC.

There are six different common register access methods:

- Fixed IO Register Access
- Fixed Memory Mapped Register Access
- IO Referenced Register Access
- Memory Referenced Register Access
- PCI Configuration Register Access (Indirect - via Memory or IO registers)
- Message Bus Register Access (Indirect - via PCI Configuration Registers)

1.1 Fixed IO Register Access

Fixed IO registers are accessed by specifying their 16-bit address in a PORT IN and/or PORT OUT transaction from the CPU core. This allows direct manipulation of the registers. Fixed IO registers are unmovable register in IO space.

Type: I/O Register (Size: 32 bits) **P80:** 80h

1.2 Fixed Memory Mapped Register Access

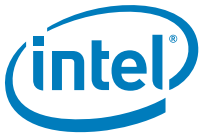
Fixed Memory Mapped IO (MMIO) registers are accessed by specifying their 32/36-bit address in a memory transaction from the CPU core. This allows direct manipulation of the registers. Fixed MMIO registers are unmovable registers in memory space.

Type: Memory Mapped I/O Register (Size: 32 bits) **IDX:** FEC00000h

1.3 IO Referenced Register Access

IO referenced registers use programmable base address registers (BARs) to select a range of IO addresses that it will use to decode PORT IN and/or PORT OUT transactions from the CPU to directly access a register. Thus, the IO BARs act as pointers to blocks of actual IO registers. To access an IO referenced register for a specific IO base address, start with that base address and add the register's offset. Example pseudo code for an IO referenced register read is shown below:

```
Register_Snapshot = IOREAD([IO_BAR]+Register_Offset)
```



Base address registers are often located in the PCI configuration space and are programmable by the BIOS/OS. Other base address register types may include fixed memory registers, fixed IO registers or message bus registers.

Type: I/O Register
(Size: 8bits)

HSTS: [PCU_IOBAR] + 0h

PCU_IOBAR Type: PCI Configuration Register (Size: 32 bits)
PCU_IOBAR Reference: [B:0, D:31, F:3] + 20h

1.4 Memory Referenced Register Access

The SoC uses programmable base address registers (BARs) to set a range of physical address (memory) locations that it will use to decode memory reads and writes from the CPU to directly access a register. These BARs act as pointers to blocks of actual memory mapped IO (MMIO) registers. To access a memory referenced register for a specific base address, start with that base address and add the register's offset. Example pseudo code for a read is shown below:

```
Register_Snapshot = MEMREAD([Mem_BAR]+Register_Offset)
```

Base address registers are often located in the PCI configuration space and are programmable by the BIOS/OS. Other common base address register types include fixed memory registers and IO registers that point to MMIO register blocks.

Type: Memory Mapped I/O Register
(Size: 8bits)

HSTS: [PCU_MBAR] + 0h

PCU_MBAR Type: PCI Configuration Register (Size: 32 bits)
PCU_MBAR Reference: [B:0, D:31, F:3] + 10h

1.5 PCI Configuration Register Access

Access to PCI configuration space registers is performed through one of two different configuration access methods (CAMs):

- IO indexed - PCI CAM
- Memory mapped - PCI Enhanced CAM (ECAM)

Each PCI function has a standard PCI header consisting of 256 bytes for the IO access scheme (CAM), or 4096 bytes for the enhanced memory access method (ECAM). Invalid read accesses return binary strings of 1s.

Type: PCI Configuration Register
(Size: 16bits)

VID: [B:0, D:31, F:3] + 0h

1.5.1 PCI Configuration Access - CAM: IO Indexed Scheme

Accesses to configuration space using the IO method relies on two 32-bit IO registers:

- **CONFIG_ADDRESS** - IO Port CF8h
- **CONFIG_DATA** - IO Port CFCh

These two registers are both 32-bit registers in IO space. Using this indirect access mode, software uses CONFIG_ADDRESS (CF8h) as an index register, indicating which configuration space register to access, and CONFIG_DATA (CFCh) acts as a window to the register pointed to in CONFIG_ADDRESS. Accesses to CONFIG_ADDRESS (CF8h) are internally captured. Upon a read or write access to CONFIG_DATA (CFCh), configuration cycles will be generated to the PCI function specified by the address captured in CONFIG_ADDRESS. The format of the address is shown below.

Table 1. PCI CONFIG_ADDRESS Register (IO PORT CF8h) Mapping

Field	CONFIG_ADDRESS Bits
Enable PCI Config. Space Mapping	31
Reserved	30:24
Bus Number	23:16
Device Number	15:11
Function Number	10:08
Register/Offset Number	07:02

Note: Bit 31 of CONFIG_ADDRESS must be set for a configuration cycle to be generated.

Pseudo code for a PCI register read is shown below:

- MyCfgAddr[23:16] = bus; MyCfgAddr[15:11] = device; MyCfgAddr[10:8] = funct;
- MyCfgAddr[7:2] = dWordMask(offset); MyCfgAddr[31] = 1;
- IOWRITE(0xCF8, MyCfgAddr)
- Register_Snapshot = IOREAD(0xCFC)

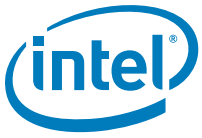
1.6 Message Bus Register Access

Accesses to the message bus space is through the SoC Transaction Router's PCI configuration registers. This unit relies on three 32-bit PCI configuration registers to generate messages:

- Message Bus Control Register (MCR) - PCI[B:0,D:0,F:0] + D0h
- Message Data Register (MDR) - PCI[B:0,D:0,F:0] + D4h
- Message Control Register eXtension (MCRX) - PCI[B:0,D:0,F:0] + D8h

This indirect access mode is similar to PCI CAM. Software uses the MCR/MCRX as an index register, indicating which message bus space register to access (MCRX only when required), and MDR as the data register. Writes to the MCR trigger message bus transactions.

Writes to MCRX and MDR will be captured. Writes to MCR will generate an internal 'message bus' transaction with the opcode and target (port, offset, bytes) specified in the MCR and the captured MCRX. When a write opcode is specified in MCR, the data



that was captured by MDR is used for the write. When a data read opcode is specified in MCR, the data will be available in the MDR register after the MCR write completes (non-posted). The format of MCR and MCRX are shown below.

Table 2. MCR Description

Field	MBPR Bits
OpCode (typically 10h for read, 11h for write)	31:24
Port	23:16
Offset/Register	15:08
Byte Enable	07:04

Table 3. MCRX Description

Field	MBPER Bits
Offset/Register Extension. This is used for messages sent to end points that require more than 8 bits for the offset/register. These bits are a direct extension of MCR[15:8].	31:08

Most message bus registers are located in the SoC Transaction Router. The default opcode messages for those registers are as follows:

- Message 'Read Register' Opcode: 06h
- Message 'Write Register' Opcode: 07h

Registers with different opcodes will be specified as applicable. Pseudo code of a message bus register read is shown below (where ReadOp==0x06):

- MyMCR[31:24] = ReadOp; MyMCR[23:16] = port; MyMCR[15:8] = offset;
- MyMCR[7:4] = 0xf
- PCIWRITE(0, 0, 0, 0xD0, MyMCR)
- Register_Snapshot = PCIREAD(0, 0, 0, 0xD4)

1.7 Register Field Access Types

Table 4. Register Access Types and Definitions

Access Type	Meaning	Description
RO	Read Only	In some cases, if a register is read only, writes to this register location have no effect. However, in other cases, two separate registers are located at the same location where a read accesses one of the registers and a write accesses the other register.
WO	Write Only	In some cases, if a register is write only, reads to this register location have no effect. However, in other cases, two separate registers are located at the same location where a read accesses one of the registers and a write accesses the other register.
R/W	Read/Write	A register with this attribute can be read and written.
R/WC	Read/Write Clear	A register bit with this attribute can be read and written. However, a write of 1 clears (sets to 0) the corresponding bit and a write of 0 has no effect.
R/WO	Read/Write-Once	A register bit with this attribute can be written only once after power up. After the first write, the bit becomes read only.
R/WLO	Read/Write, Lock-Once	A register bit with this attribute can be written to the non-locked value multiple times, but to the locked value only once. After the locked value has been written, the bit becomes read only.
Default	Default	When the processor is reset, it sets its registers to predetermined default states. The default state represents the minimum functionality feature set required to successfully bring up the system. Hence, it does not represent the optimal system configuration. It is the responsibility of the system initialization software to determine configuration, operating parameters, and optional system features that are applicable, and to program the processor registers accordingly.

2 Mapping Address Spaces

The SoC supports four different address spaces:

- Physical Address Space Mappings
- IO Address Space
- PCI Configuration Space
- Message Bus Space

The CPU core can only directly access *memory space* through memory reads and writes and *IO space* through the IN and OUT IO port instructions. *PCI configuration space* is indirectly accessed through IO or memory space, and the *Message Bus space* is accessed through PCI configuration space. Refer Chapter 1, "Register Access Methods" for details.

This chapter describes how the memory, IO, PCI and Message Bus spaces are mapped to interfaces in the SoC.

2.1 Physical Address Space Mappings

There are 64 GB (36-bits) of physical address space that can be used as:

- Memory Mapped IO (MMIO - IO fabric)
- Physical Memory (DRAM)

The CPU core can access the full physical address space, while downstream devices can only access SoC DRAM, and each CPU core's local APIC. Peer to peer transactions are not supported.

Most devices map their registers and memory to the physical address space. This chapter summarizes the possible mappings.

2.1.1 SoC Transaction Router Memory Map

The SoC Transaction Router maps the physical address space as follows:

- CPU core to DRAM
- CPU core to IO fabric (MMIO)
- CPU core to extended PCI registers (ECAM accesses)
- IO fabric to CPU cores (local APIC interrupts)

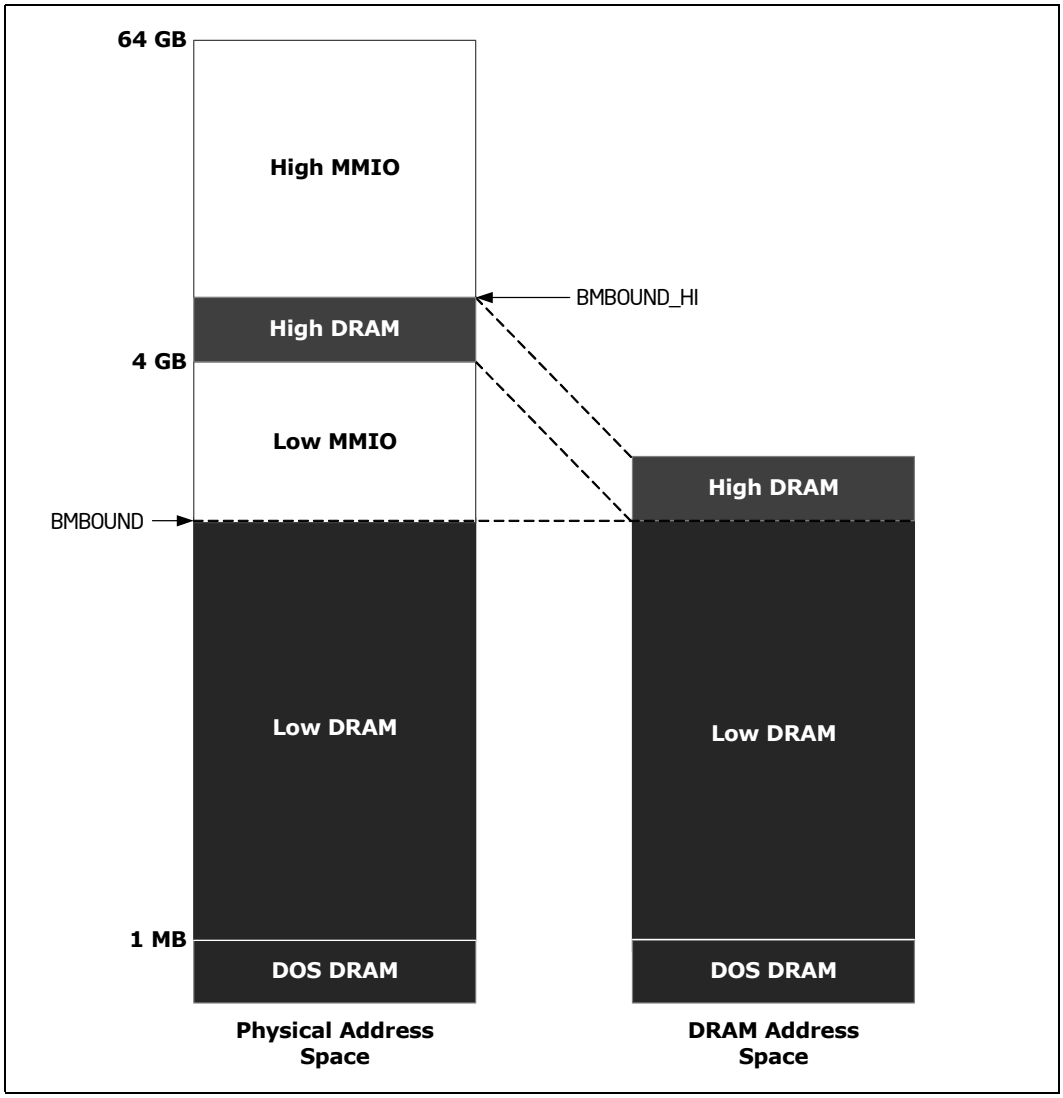
Although 64 GB (36-bits) of physical address space is accessible, some MMIO must exist for devices and software with 32-bit limits. Further, all DRAM should remain accessible for devices and software with access to memory above 4 GB. These goals

are accomplished by moving a section DRAM to start at the fixed 4 GB boundary, leaving a hole below 4 GB for MMIO. This creates the following distinct memory regions:

- DOS DRAM + Low DRAM
- Low MMIO
- High DRAM
- High MMIO

There are two registers used to create these regions, BMBOUND and BMBOUND_HI. Their use is shown in Figure 1.

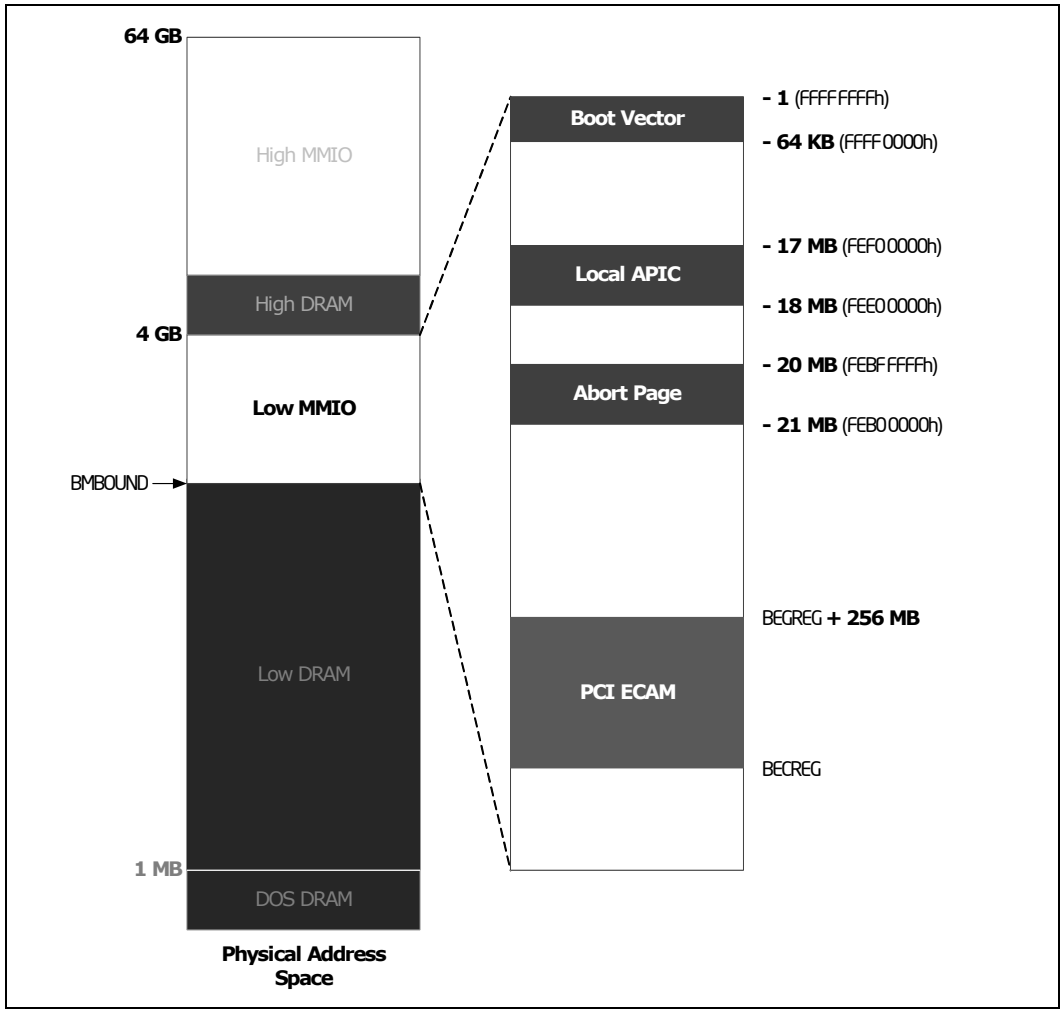
Figure 1. Physical Address Space - DRAM & MMIO



2.1.1.1 Low MMIO

The low MMIO mappings are shown in Figure 2.

Figure 2. Physical Address Space - Low MMIO



By default, CPU core reads targeting the **Boot Vector** range (FFFFFFFFh-FFFF0000h) are sent to the boot Flash connected to the Platform Controller Unit, and write accesses target DRAM. This allows the boot strap CPU core to fetch boot code from the boot Flash, and then shadow that code to DRAM.

Upstream writes from the IO fabric to the **Local APIC** range (FEE00000h-FEF00000h) are sent to the appropriate CPU core's APIC.

Write accesses from a CPU core to the **Abort Page** range (FEB00000h-FEBFFFFFh) will be dropped, and reads will always return all 1's in binary.

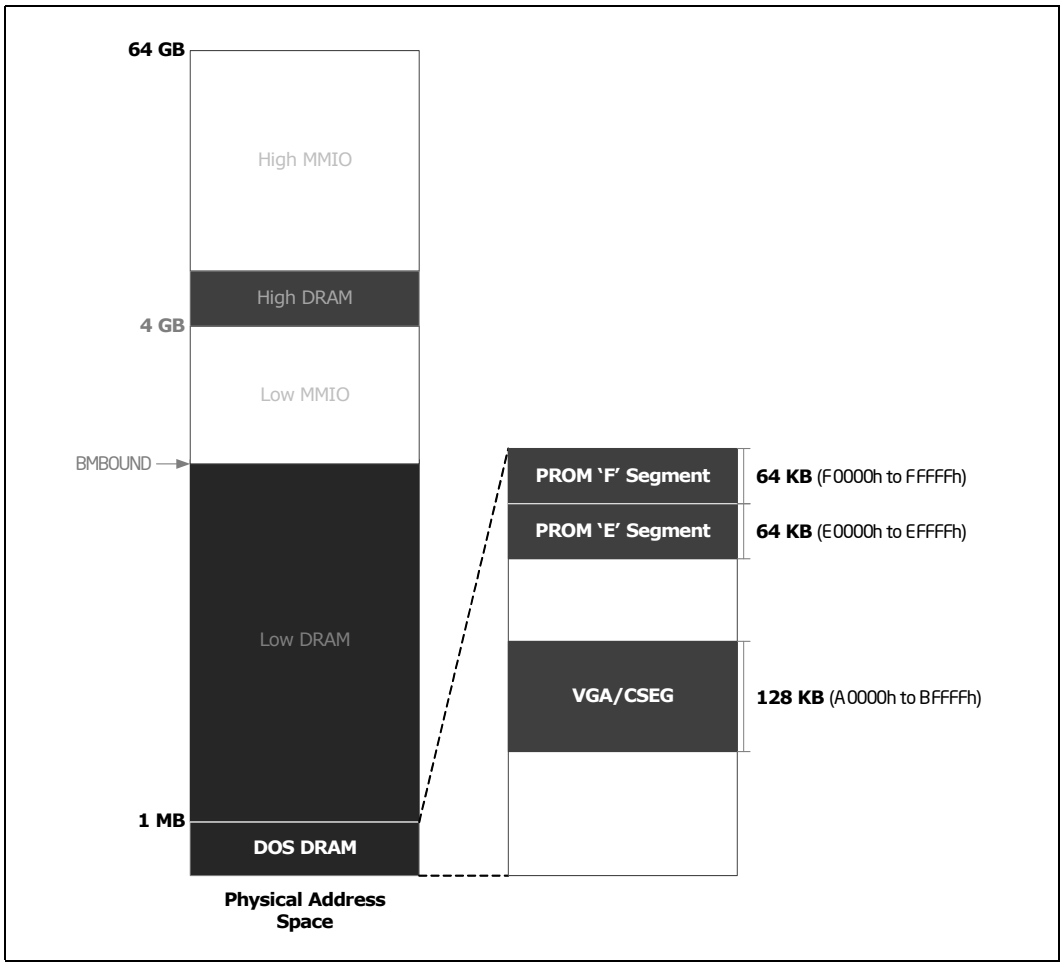
Accesses in the 256 MB **PCI ECAM** range starting at BECREG generate enhanced PCI configuration register accesses when enabled (BECREG.ECENABLE). Unlike traditional memory writes, writes to this range are non-posted when enabled. Refer Chapter 1, "Register Access Methods" for more details.

All other downstream accesses in the Low MMIO range are sent to the IO Fabric for further decode based on PCI resource allocations. The IO Fabric's subtractive agent (for unclaimed accesses) is the Platform Controller Hub.

2.1.1.2 DOS DRAM

The DOS DRAM is the memory space below 1 MB. In general, accesses from a processor targeting DOS DRAM target system DRAM. Exceptions are shown in the below figure.

Figure 3. Physical Address Space - DOS DRAM



Processor writes to the 64 KB (each) **PROM 'E'** and **'F'** segments (E0000h-EFFFFh and F0000h-FFFFFh) always target DRAM. The BMISC register is used to direct CPU core reads in these two segments to DRAM or the IO fabric (MMIO).

CPU core accesses to the 128 KB **VGA/CSEG** range (A0000h-BFFFFh) can target DRAM or the IO fabric (MMIO). The target is selected with the BMISC.ABSEGINDRAM register.

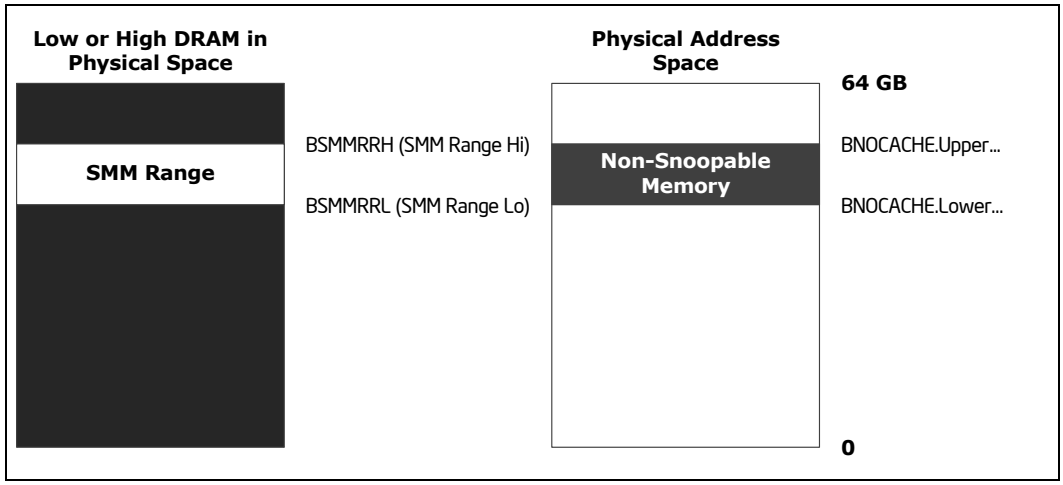
2.1.1.3 Additional Mappings

There are two additional mappings available in the SoC Transaction Router:

- SMM range
- Non-snoop range

Figure 4 shows these mappings.

Figure 4. Physical Address Space - SMM and Non-Snoop Mappings



SMI handlers running on a CPU core execute out of SMM memory. To protect this memory from non-CPU core access, the **SMM Range** (BSMMRRL-BSMMRRH) may be programmed anywhere in low or high DRAM space (1 MB aligned). This range will only allow accesses from the CPU cores.

To prevent snoops of the CPU cores when DMA devices access a specific memory region, the **Non-Snoopable Memory range** (BNOCACHE.Lower-BNOCACHE.Upper) can be programmed anywhere in physical address space. This range is enabled via the BNOCACHECTL register's enable bit (BNOCACHECTL.Enable).

2.1.2 IO Fabric (MMIO) Map

Memory accesses targeting MMIO are routed by the IO fabric to programmed PCI ranges, or routed to the PCU by default (subtractive agent). Programmed PCI ranges can be moved within low or high MMIO, and most can be disabled.

Note: Not all devices can be mapped to high MMIO.

Fixed MMIO is claimed by the Platform Controller Unit (PCU). The default regions are listed below. Movable ranges are not shown.

Table 5. Fixed Memory Ranges in the Platform Controller Unit (PCU)

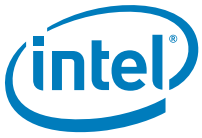
Device	Start Address	End Address	Comments
Low BIOS (Flash Boot)	000E0000h	000FFFFFh	Starts 128 KB below 1 MB; Firmware/ BIOS
IO APIC	FEC00000h	FEC00040h	Starts 20 MB below 4 GB
HPET	FED00000h	FED003FFh	Starts 19 MB below 4 GB
TPM (LPC)	FFD40000h	FFD40FFFh	Starts 16 KB above HPET range
High BIOS/Boot Vector	FFFF0000h	FFFFFFFFh	Starts 64 KB below 4 GB; Firmware/ BIOS

The following PCI devices may claim memory resources in MMIO space:

- Graphics/Display (High MMIO capable)
- SD/MMC/SDIO
- SIO
- Platform Controller Unit (PCU) (Multiple BARs)
- xHCI USB
- EHCI USB
- USB Device
- ISP/MIPI-CSI

Refer each device’s interface chapter for details.

Warning: Variable memory ranges should not be set to conflict with other memory ranges. There will be unpredictable results if the configuration software allows conflicts to occur. Hardware does not check for conflicts.



2.2 IO Address Space

There are 64 KB + 3 bytes of IO space (0h-10002h) for accessing IO registers. Most IO registers exists for legacy functions in the PCU or for PCI devices, while some are claimed by the SoC Transaction Router for graphics and for the PCI configuration space access registers.

2.2.1 SoC Transaction Router IO Map

The SoC claims IO transactions for VGA/Extended VGA found in the display/graphics interface. It also claims the two 32-bit registers at port CF8h and CFCh used to access PCI configuration space.

2.2.2 IO Fabric IO Map

2.2.2.1 PCU Fixed IO Address Ranges

Sequencer Index

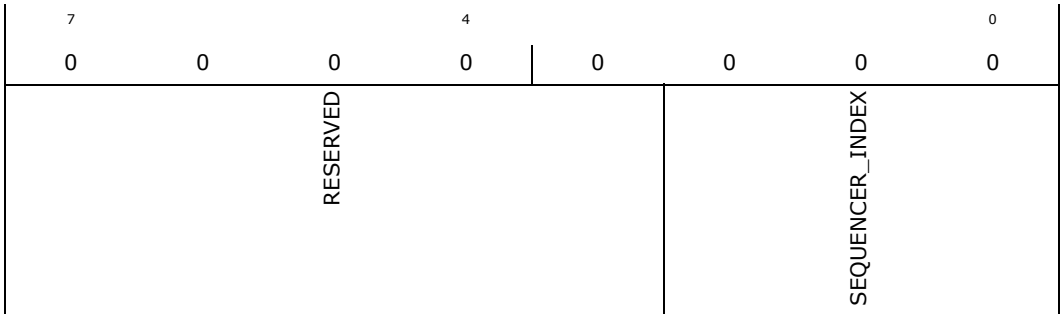
Access Method

Type: Memory Mapped I/O Register (Size: 8 bits)

SRX: [GTTMMADR_LSB + 2BF20h] + 3C4h

GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)
GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

Default: 00h



Bit Range	Default & Access	Description
7:3	0b RW	**RESERVED:** Read as 0s.
2:0	0b RW	**SEQUENCER_INDEX:** This field contains a 3-bit Sequencer Index value used to access sequencer data registers at indices 0 through 7. Notes: SR02 is referred to in the VGA standard as the Map Mask Register. However, the word map is used with multiple meanings in the VGA standard and was, therefore, deemed too confusing; hence, the reason for calling it the Plane Mask Register. SR07 is a standard VGA register that was not documented by IBM. It is not a graphics controller extension.

3.1.6 SR—Offset 3C5h

3.1.7 DACMASK—Offset 3C6h

Pixel Data Mask Register

Access Method

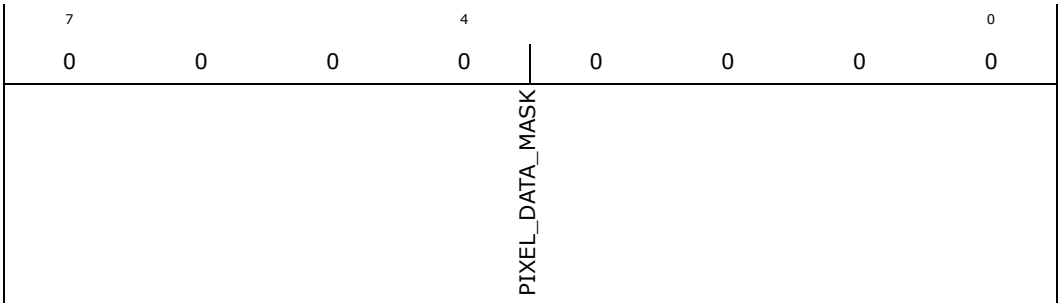
Type: Memory Mapped I/O Register (Size: 8 bits)

DACMASK: [GTTMMADR_LSB + 2BF20h] + 3C6h

GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)

GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

Default: 00h



Bit Range	Default & Access	Description
7:0	0b RW	**PIXEL_DATA_MASK:** In indexed-color mode, the 8 bits of this register are logically ANDed with the 8 bits of pixel data received from the frame buffer for each pixel. The result of this ANDing process becomes the actual index used to select color data positions within the palette. This has the effect of limiting the choice of color data positions that may be specified by the incoming 8-bit data. 0 = Corresponding bit in the resulting 8-bit index being forced to 0. 1 = Allows the corresponding bit in the resulting index to reflect the actual value of the corresponding bit in the incoming 8-bit pixel data.

3.1.8 DACWX—Offset 3C8h

Palette Write Index Register

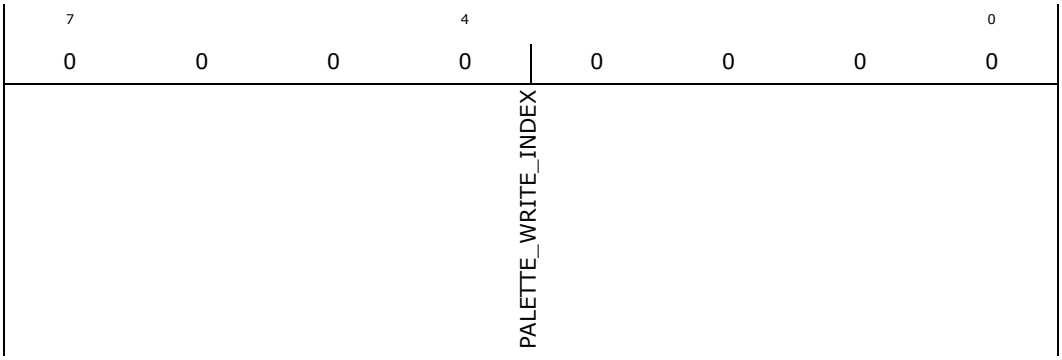
Access Method

Type: Memory Mapped I/O Register (Size: 8 bits)

DACWX: [GTTMMADR_LSB + 2BF20h] + 3C8h

GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)
GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

Default: 00h



Bit Range	Default & Access	Description
7:0	0b WO	**PALETTE_WRITE_INDEX:** The 8-bit index value programmed into this register chooses which of 256 standard color data positions within the palette are to be made accessible for being written via the Palette Data Register (DACDATA). The index value held in this register is automatically incremented when all three bytes of the color data position selected by the current index have been written. This register allows access to the palette even when running non-VGA display modes.

3.1.9 DACDATA—Offset 3C9h

Palette Data Register

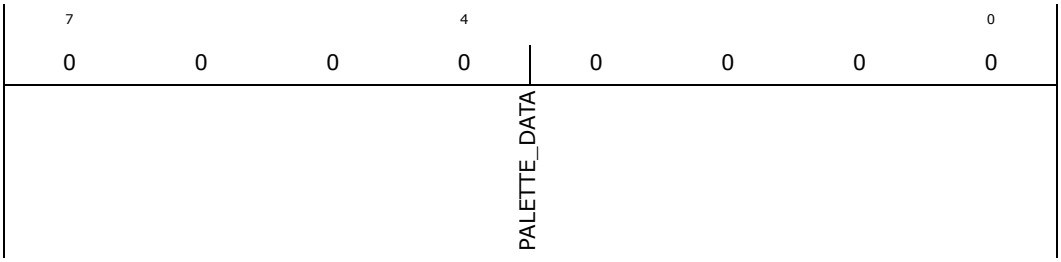
Access Method

Type: Memory Mapped I/O Register (Size: 8 bits)

DACDATA: [GTTMMADR_LSB + 2BF20h] + 3C9h

GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)
GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

Default: 00h



Bit Range	Default & Access	Description
7:0	0b RW	**PALETTE_DATA:** This byte-wide data port provides read or write access to the three bytes of data of each color data position selected using the Palette Read Index Register (DACRX) or the Palette Write Index Register (DACWX). The three bytes in each color data position are read or written in three successive read or write operations. The first byte read or written specifies the intensity of the red component of the color specified in the selected color data position. The second byte is for the green component, and the third byte is for the blue component. When writing data to a color data position, all three bytes must be written before the hardware will actually update the three bytes of the selected color data position. When reading or writing to a color data position, ensure that neither the Palette Read Index Register (DACRX) or the Palette Write Index Register (DACWX) are written to before all three bytes are read or written. A write to either of these two registers causes the circuitry that automatically cycles through providing access to the bytes for red, green and blue components to be reset such that the byte for the red component is the one that will be accessed by the next read or write operation via this register. This register allows access to the palette even when running non-VGA display modes. Writes to the palette can cause sparkle if not done during inactive video periods. This sparkle is caused by an attempt to write and read the same address on the same cycle. Anti-sparkle circuits will substitute the previous pixel value for the read output.

Bit Range	Default & Access	Description
7	0b RW	**CRT_VSYNC_POLARITY:** This is a legacy function that is used in native VGA modes. For most cases, sync polarity will be controlled by the port control bits. The VGA settings can be optionally selected for compatibility with the original VGA when used in the VGA native mode. Sync polarity was used in VGA to signal the monitor how many lines of active display are being generated. 0 = Positive Polarity (default). 1 = Negative Polarity.
6	0b RW	**CRT_HSYNC_POLA_RITY:** This is a legacy function that is used in native VGA modes. For most cases, sync polarity will be controlled by the port control bits. The VGA settings can be optionally selected for compatibility with the original VGA when used in the VGA native mode. 0 = Positive Polarity (default). 1 = Negative Polarity
5	0b RW	**PAGE_SELECT:** In Odd/Even Memory Map Mode 1 (GR6), this bit selects the upper or lower 64 KB page in dis play memory for CPU access: 0 = Upper page (default) 1 = Lower page. Selects between two 64KB pages of frame buffer memory during standard VGA odd/even modes (modes 0h through 5h). Bit 1 of register GR06 can also program this bit in other modes. Note that this bit is would normally set to 1 by the software.
4	0b RW	**RESERVED:** Read as 0.
3:2	0b RW	**CLOCK_SELECT:** These bits can select the dot clock source for the CRT interface. The bits should be used to select the dot clock in standard native VGA modes only. When in the centering or upper left corner modes, these bits should be set to have no effect on the clock rate. The actual frequencies that these bits select, if they have any affect at all, is programmable through the DPLL registers that default to the standard values used for VGA. 00 = CLK0, 25.175 MHz (for standard VGA modes with 640 pixel (8-dot) horizontal resolution) (default) 01 = CLK1, 28.322 MHz. (for standard VGA modes with 720 pixel (9-dot) horizontal resolution) 10 = Was used to select an external clock (now unused) 11 = Reserved

Bit Range	Default & Access	Description

When disabled, accesses to VGA memory are blocked in this region. This bit is independent of and does not block CPU access to the video linear frame buffer at other addresses. Note that it is typical for AGP chipsets to shadow this register to allow proper steering of memory accesses to the proper bus. 0 = Prevent CPU access to memory/registers/ROM through the A0000-BFFFF VGA memory aperture (default). 1 = Allow CPU access to memory/registers/ ROM through the A0000-BFFFF VGA memory aperture. This memory must be mapped as UC by the CPU; see VGA Host Access Memory Munging in Display and Overlay Functions.
0	0b RW	**I_O_ADDRESS_SELECT:** This bit selects 3Bxh or 3Dxh as the I/O address for the CRT Controller registers, the Feature Control Register (FCR), and Input Status Register 1 (ST01). Presently ignored (whole range is claimed), but will ignore 3Bx for color configuration or 3Dx for monochrome. Note that it is typical in AGP chipsets to shadow this bit and properly steer I/O cycles to the proper bus for operation where a MDA exists on another bus such as ISA. 0 = Select 3Bxh I/O address (MDA emulation) (default). 1 = Select 3Dxh I/O address (CGA emulation).

Bit Range	Default & Access	Description
31	0b RW	**SOFTWARE_CLEAR_INTERRUPT_SW_CLR_INT:** This bit must be clear for normal operation. Setting the bit , then clearing it acts as local reset to the GMBUS controller. This bit is commonly used by software to clear a BUS_ERROR when a slave device delivers a NACK. 0 = If this bit is written as a zero when its current state is a one, will clear the HW_RDY bit and allows register writes to be accepted to the GMBUS registers (Write Protect Off). This bit is cleared to zero when an event causes the HW_RDY bit transition to occur. 1 = Asserted by software after servicing the GMBUS interrupt. Setting this bit causes the INT status bit to be cleared. Setting (1) this bit also asserts the HW_RDY bit (until this bit is written with a 0). When this bit is set, no writes to GMBUS registers will cause the contents to change with the exception of this bit which can be written.
30	0b RW	**SOFTWARE_READY_SW_RDY:** Data handshake bit used in conjunction with HW_RDY bit. 0 = De-asserted via the assertion event for HW_RDY bit 1 = When asserted by software, results in de-assertion of HW_RDY bit
29	0b RW	**ENABLE_TIMEOUT_ENT:** Enables timeout for slave response. When this bit is enabled and the slave device response has exceeded the timeout period, the GMBUS Slave Stall Timeout Error interrupt bit is set. 0 = disable timeout counter 1 = enable timeout counter
28	0b RW	**RESERVED:** Reserved.
27:25	0b RW	**BUS_CYCLE_SELECT:** 000 = No GMBUS cycle is generated. 001 = GMBUS cycle is generated without an INDEX, with no STOP, and ends with a WAIT 010 = Reserved 011 = GMBUS cycle is generated with an INDEX, with no STOP, and ends with a WAIT 100 = Generates a STOP if currently in a WAIT or after the completion of the current byte if active. 101 = GMBUS cycle is generated without an INDEX and with a STOP 110 = Reserved 111 = GMBUS cycle is generated with an INDEX and with a STOP GMBUS cycle will always consist of a START followed by Slave Address, followed by an optional read or write data phase. A read cycle with an index will consist of a START followed by a Slave Address a WRITE indication and the INDEX and then a RESTART with a Slave Address and an optional read data phase. The GMBUS cycle will terminate either with a STOP or by entering a wait state. The WAIT state is exited by generating a STOP or by starting another GMBUS cycle. This can only cause a STOP to be generated if a GMBUS cycle is generated, the GMBUS is currently in a data phase, or it is in a WAIT phase: Note that the three bits can be decoded as follows: 27 = STOP generated 26 = INDEX used 25 = cycle ends in a WAIT
24:16	0b RW	**TOTAL_BYTE_COUNT:** (9-bits). This determines the total number of bytes to be transferred during the DATA phase of a GMBUS cycle. The DATA phase can be prematurely terminated by generating a STOP while in the DATA phase (see Bus Cycle Select). Do not change the value of this field during GMBUS cycles transactions.
15:8	0b RW	**_8_BIT_GMBUS_SLAVE_REGISTER_INDEX_INDEX:** This field specifies the 8-bits of index to be used for the generated bus write transaction or the index used for the WRITE portion of the WRITE/READ pair. It only has an effect if the enable Index bit is set. Do not change this field during a GMBUS transaction.

Bit Range	Default & Access	Description
7:1	0b RW	**_7_BIT_GMBUS_SLAVE_ADDRESS_SADDR:** When a GMBUS cycle is to be generated using the Bus Cycle Select field, this field specifies the value of the slave address that is to be sent out. For use with 10-bit slave address devices, set this value to 11110XXb (where the last two bits (xx) are the two MSBs of the 10-bit address) and the slave direction bit to a write. This is followed by the first data byte being the 8 LSBs of the 10-bit slave address. Special Slave Addresses 0000 000R = General Call Address 0000 000W = Start byte 0000 001x = CBUS Address 0000 010x = Reserved 0000 011x = Reserved 0000 1xxx = Reserved 1111 1xxx = Reserved 1111 0xxx = 10-Bit addressing
0	0b RW	**SLAVE_DIRECTION_BIT:** When a GMBUS cycle is to be generated based on the Bus Cycle Select, this bit determines if the operation will be a read or a write. A read operation with the index enabled will perform a write with just the index followed by a re-start and a read. 1 = Indicates that a Read from the slave device operation is to be performed. 0 = Indicates that a Write to slave device operation is to be performed.

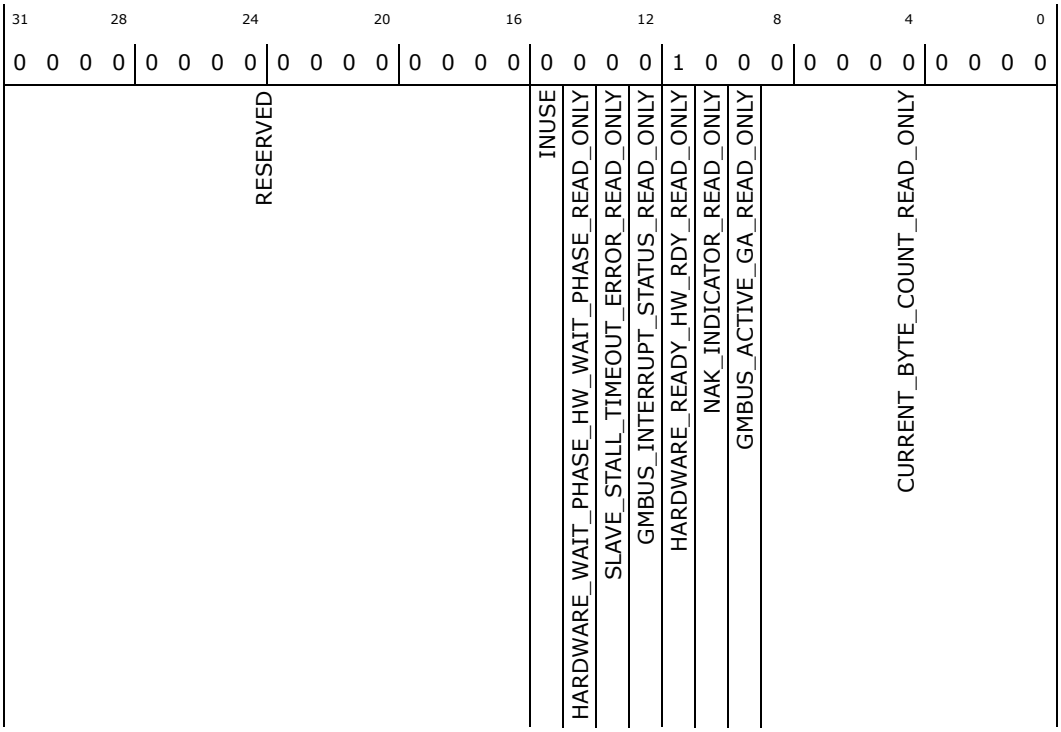
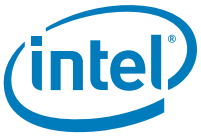
Default: 00000800h



Bit Range	Default & Access	Description
31:16	0b RW	**RESERVED:** Reserved.
15	0b RW/1C	**INUSE:** 0 = read operation that contains a zero in this bit position indicates that the GMBUS engine is now acquired and the subsequent reads of this register will now have this bit set. Writing a 0 to this bit has no effect. 1 = read operation that contains a one for this bit indicates that the GMBUS is currently allocated to someone else and In use . Once set, a write of a 1 to this bit indicates that the software has relinquished the GMBUS resource and will reset the value of this bit to a 0. Software wishing to arbitrate for the GMBUS resource can poll this bit until it reads a zero and will then own usage of the GMBUS controller. This bit has no effect on the hardware, and is only used as semaphore among various independent software threads that don t know how to synchronize their use of this resource that may need to use the GMBUS logic. Writing a one to this bit is software s indication that the software use of this resource is now terminated and it is available for other clients. AccessType: One to clear
14	0b RO	**HARDWARE_WAIT_PHASE_HW_WAIT_PHASE_READ_ONLY:** 0 = The GMBUS engine is not in a wait phase. 1 = Set when GMBUS engine is in wait phase. Wait phase is entered at the end of the current transaction when that transaction is selected not to terminate with a STOP. Once in a WAIT_PHASE, the software can now choose to generate a STOP cycle or a repeated start (RESTART) cycle followed by another GMBUS transaction on the GMBUS. AccessType: Read Only



Bit Range	Default & Access	Description
13	0b RO	**SLAVE_STALL_TIMEOUT_ERROR_READ_ONLY:** This bit indicates that a slave stall timeout has occurred. It is tied to the Enable Timeout (ENT) bit. 0 = No slave timeout has occurred. 1 = A slave acknowledge timeout has occurred AccessType: Read Only
12	0b RO	**GMBUS_INTERRUPT_STATUS_READ_ONLY:** This bit indicates that an event that causes a GMBUS interrupt has occurred. 0 = The conditions that could cause a GMBUS interrupt have not occurred or this bit has been cleared by software assertion of the SW_CLR_INT bit. 1 = GMBUS interrupt event occurred. This interrupt must have been one of the types enabled in the GMBUS4 register. [DevCDV, DevCTG]: Reserved AccessType: Read Only
11	1b RO	**HARDWARE_READY_HW_RDY_READ_ONLY:** This provides a method of detecting when the current software client routine can proceed with the next step in a sequence of GMBUS operations. This data handshake bit is used in conjunction with the SW_RDY bit. When this bit is changed to asserted by the GMBUS controller, it results in the de-assertion of the SW_RDY bit. 0 = Condition required for assertion has not occurred or when this bit was a one and: SW_RDY bit has been asserted. During a GMBUS read transaction, after the each read of the data register. During a GMBUS write transaction, after each write of the data register. SW_CLR_INT bit has been cleared. 1 = This bit is asserted under the following conditions: After a reset or when the transaction is aborted by the setting of the SW_CLR_INT bit. When an active GMBUS cycle has terminated with a STOP. When during a GMBUS write transaction, the data register needs and can accept another four bytes of data. During a GMBUS read transaction, this bit is asserted when the data register has four bytes of new data or the read transaction DATA phase is complete and the data register contains the last few bytes of the read data. This bit resumes to normal operation when the SW_CLR_INT bit is written to a 0. AccessType: Read Only
10	0b RO	**NAK_INDICATOR_READ_ONLY:** Was previously called Slave Acknowledge Timeout Error SATOER. 0 = No bus error has been detected or SW_CLR_INT has been written as a zero since the last bus error. 1 = Set by hardware if any expected device acknowledge is not received from the slave within the timeout. AccessType: Read Only
9	0b RO	**GMBUS_ACTIVE_GA_READ_ONLY:** This is a status bit that indicates whether the GMBUS controller is in an IDLE state or not. 0 = The GMBUS controller is currently IDLE. 1 = This indicates that the bus is in START, ADDRESS, INDEX, DATA, WAIT, or STOP Phase. Set when GMBUS hardware is not IDLE. AccessType: Read Only
8:0	0b RO	**CURRENT_BYTE_COUNT_READ_ONLY:** Can be used to determine the number of bytes currently transmitted/received by the GMBUS controller hardware. Set to zero at the start of a GMBUS transaction data transfer and incremented after the completion of each byte of the data phase. Note that because reads have internal storage, the byte count on a read operation may be ahead of the data that has been accepted from the data register. AccessType: Read Only

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)

Bit Range	Default & Access	Description
31:29	0b RW	**RESERVED:** Write as zero.
28:16	0b RW	**PIPE_A_HORIZONTAL_TOTAL_DISPLAY_CLOCKS:** This 13-bit field provides Horizontal Total up to 8192 pixels encompassing the Horizontal Active Display period, front/back border and retrace period. Any pending event (HSYNC, ACTIVE, HBLANK) is reset at HTOTAL and the programmed sequence begins again. This field is programmed to the number of clocks desired minus one. This number of clocks needs to be a multiple of two when driving data out the digital port out the LVDS port in two channel mode. This value should always be equal or greater to the sum of the horizontal active and the horizontal blank, and border region sizes.
15:12	0b RW	**RESERVED_1:** Write as zero.

Bit Range	Default & Access	Description
11:0	0b RW	**PIPE_A_HORIZONTAL_ACTIVE_DISPLAY_END_PIXELS:** This 12-bit field provides Horizontal Active Display resolutions up to 4096 pixels. **NOTE:** The first horizontal active display pixel is considered pixel number 0. The value programmed should be the (active pixels/line 1). The number of active pixels will be limited to multiples of two pixels when driving the integrated LVDS port in two channel mode. For proper results during VGA centering mode this value needs to be large enough to fit the largest VGA mode supported, this should be at least 720/1440 pixels for standard VGA type modes or 640/1280 pixels if the nine-dot disable bit in the VGA control register is set. When using the internal panel fitting logic, the minimum horizontal size allowed will be three pixels.

3.1.151 HBLANK_A—Offset 60004h

Pipe A Horizontal Blank Register

Access Method

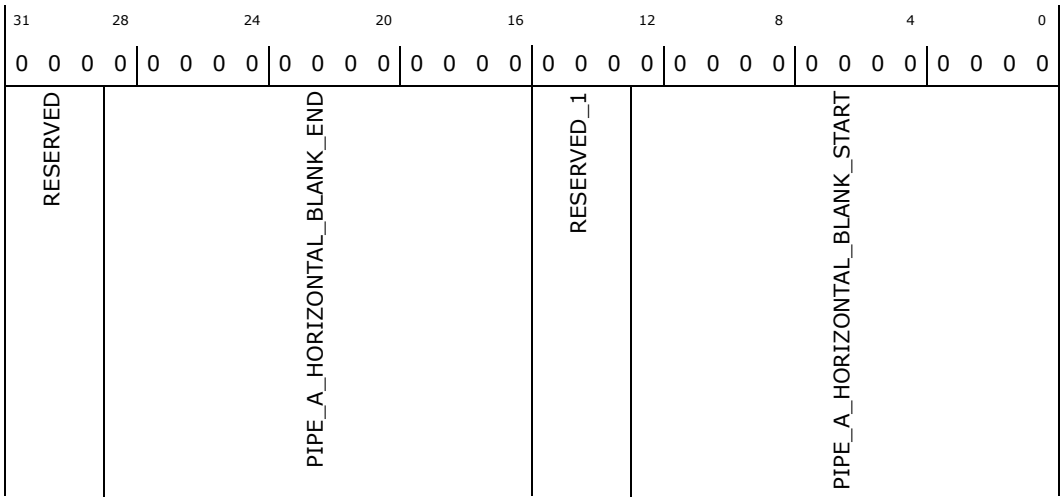
Type: Memory Mapped I/O Register (Size: 32 bits)

HBLANK_A: [GTTMMADR_LSB + 2BF20h] + 60004h

GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)

GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0b RW	**RESERVED:** Read Only.

Bit Range	Default & Access	Description
28:16	0b RW	**PIPE_A_HORIZONTAL_BLANK_END:** This 13-bit field specifies the position of Horizontal Blank End expressed in terms of the absolute pixel number relative to the horizontal active display start. The value programmed should be the HBLANK End pixel position, where the first active pixel is considered position 0; the second active pixel is considered position 1, etc. Horizontal blank ending at the same point as the horizontal total indicates that there is no left hand border area. HBLANK size has a minimum value of 32 clocks. The number of clocks within blank needs to be a multiple of two when driving data out LVDS in two channel mode. The value loaded in the register would be equal to RightBorder+Active+HBlank-1. If this pipe is connected to the TVout port or Panel Fitter 2 the border must be zero. In that case this register is programmed to the same value as the HTOTAL register.
15:13	0b RW	**RESERVED_1:** Read Only.
12:0	0b RW	**PIPE_A_HORIZONTAL_BLANK_START:** This 13-bit field specifies the Horizontal Blank Start position expressed in terms of the absolute pixel number relative to the horizontal active display start. The value programmed should be the HBLANK Start pixel position, where the first active pixel is considered position 0; the second active pixel is considered position 1, etc. The number of clocks for both left and right borders need to be a multiple of two when driving data out the LVDS port in two channel mode. Horizontal blank should only start after the end of the horizontal active region. The value loaded in the register would be equal to RightBorder+Active-1. If this pipe is connected to the TVout port or Panel Fitter 2 the border must be zero. In that case this register is programmed to the same value as the HACTIVE register.

3.1.152 HSYNC_A—Offset 60008h

Bit Range	Default & Access	Description
31:29	0b RW	**RESERVED:** Write as zero.
28:16	0b RW	**PIPE_A_HORIZONTAL_SYNC_END:** This 13-bit field specifies the horizontal Sync End position expressed in terms of the absolute pixel number relative to the horizontal active display start. The value programmed should be the HSYNC End pixel position, where the first active pixel is considered position 0; the second active pixel is considered position 1, etc. The number of clocks in the sync period needs to be a multiple of two when driving data out the LVDS port in two channel mode. This value should be greater than the horizontal sync start position and would be loaded with the Active+RightBorder+FrontPorch+Sync-1.
15:13	0b RW	**RESERVED_1:** Read Only.
12:0	0b RW	**PIPE_A_HORIZONTAL_SYNC_START:** This 13-bit field specifies the horizontal Sync Start position expressed in terms of the absolute pixel number relative to the horizontal active display start. The value programmed should be the HSYNC Start pixel position, where the first active pixel is considered position 0; the second active pixel is considered position 1, etc. Note that when HSYNC Start is programmed equal to HBLANK Start, both HSYNC and HBLANK will be asserted on the same pixel clock. It should never be programmed to less than HBLANK start. The number of cycles from the beginning of the line needs to be a multiple of two when driving data out the LVDS port in two channel mode. This register should not be less than the horizontal active end. This register should be loaded with the Active+RightBorder+FrontPorch-1.

3.1.153 VTOTAL_A—Offset 6000Ch

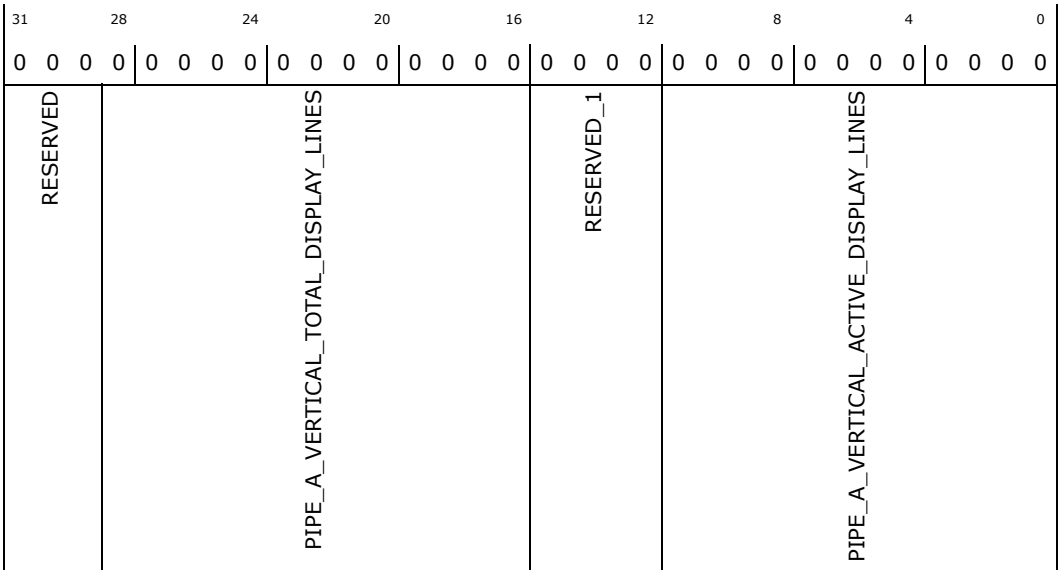
GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)

GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0b RW	**RESERVED:** Read Only.
28:16	0b RW	**PIPE_A_VERTICAL_TOTAL_DISPLAY_LINES:** This 13 bit field provides Vertical Total up to 8192 lines encompassing the Vertical Active Display Lines, top/bottom border and retrace period. The value programmed should be the number of lines required minus one. Vertical total needs to be large enough to be greater than the sum of the vertical active, vertical border, and the vertical blank regions. The vertical counter is incremented on the leading edge of the horizontal sync. For interlaced display modes, this indicates the total number of lines in both fields. In interlaced modes, hardware automatically divides this number by 2 to get the number of lines in each field.
15:12	0b RW	**RESERVED_1:** Read Only.
11:0	0b RW	**PIPE_A_VERTICAL_ACTIVE_DISPLAY_LINES:** This 12-bit field provides vertical active display resolutions up to 4096 lines. It should be programmed with the desired number of lines minus one. When using the internal panel fitting logic, the minimum vertical active area must be three lines. For interlaced display modes, this indicates the total number of lines in both fields. In interlaced modes, hardware automatically divides this number by 2 to get the number of lines in each field.

28:16	0b RW	**PIPE_A_VERTICAL_BLANK_END:** This 13-bit field specifies the Vertical Blank End position expressed in terms of the absolute Line number relative to the vertical active display start. The value programmed should be the VBLANK End line position, where the first active line is considered line 0, the second active line is considered line 1, etc. The end of vertical blank should be after the start of vertical blank and before or equal to the vertical total. This register should be loaded with the Vactive+BottomBorder+VBlank-1. For interlaced display modes, hardware automatically divides this number by 2 to get the vertical blank end in each field. It does not count the two half lines that get added when operating in modes with half lines. If this pipe is connected to the TVout port or Panel Fitter 2 the border must be zero. In that case this register is programmed to the same value as the VTOTAL register.
15:13	0b RW	**RESERVED_1:** Read Only.

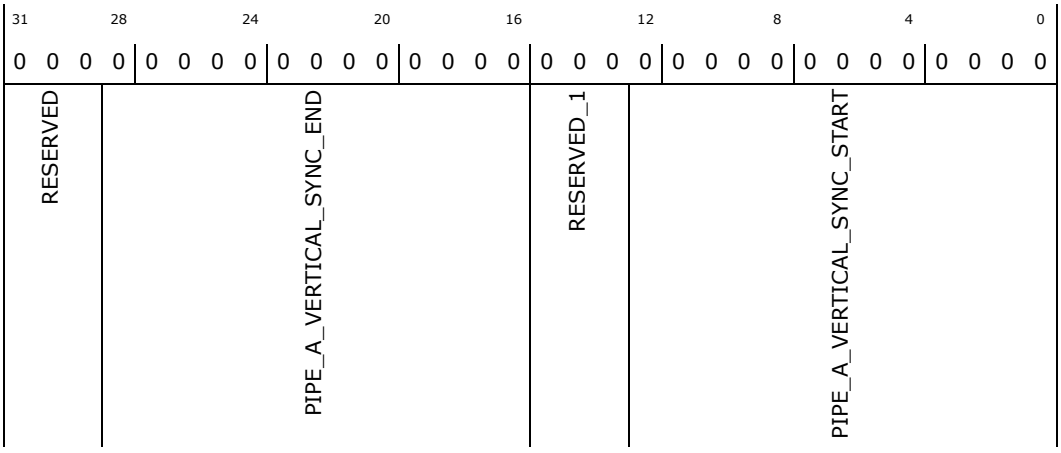
GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)
GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:28	0b RW	**RESERVED:** Write as zero
27:16	0b RW	**PIPE_A_HORIZONTAL_SOURCE_IMAGE_SIZE:** This 12-bit field specifies Horizontal source image size up to 4096. This determines the size of the image created by the display planes sent to the blender. The value programmed should be the source image size minus one. The actual source size must be two times the programmed value in the pixel multiply mode. It must represent a size that is a multiple of two (even numbers) when driving the LVDS port in two channel mode. This implies that for this mode, the value programmed will always be an odd number. Except in the case of panel fitting internal or in an external device, this register field would be programmed to a value identical to the horizontal active. This is the only register of the timing registers that is allowed to be programmed while the pipe is enabled.
15:12	0b RW	**RESERVED_1:** Write as zero
11:0	0b RW	**PIPE_A_VERTICAL_SOURCE_IMAGE_SIZE:** This 12-bit field specifies the vertical source image size up to 4096 lines. This determines the size of the image created by the display planes sent to the blender. The value programmed should be the source image size minus one. Note that the actual number of lines needs to be at least twice the planes programmed value when in the pixel multiply mode. Except in the case of panel fitting internal or in an external device, this register field would be programmed to a value identical to the vertical active. For interlaced display modes, hardware automatically divides this number by 2 to get the vertical source image size in each field.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

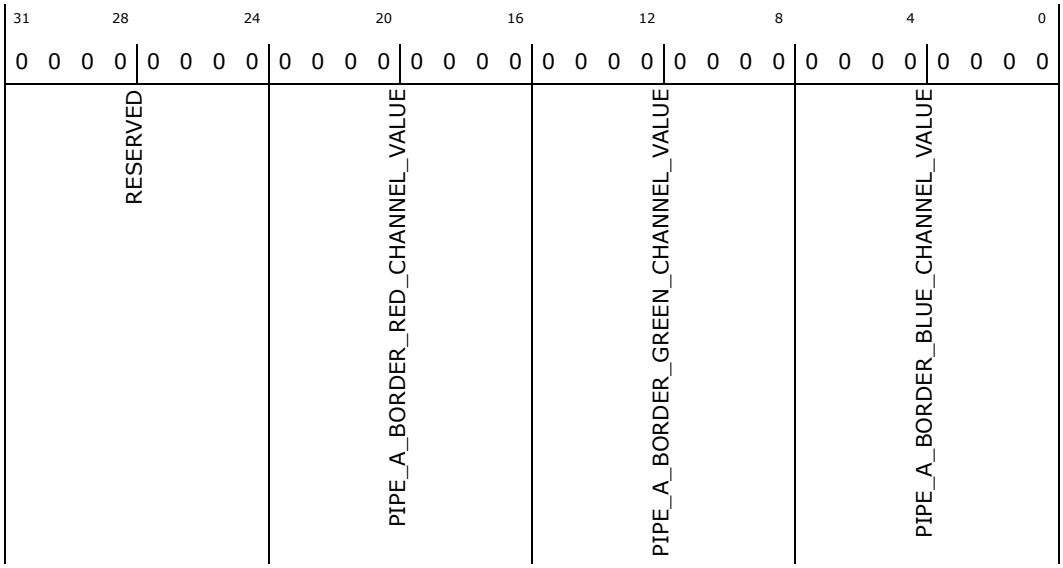
GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)
GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:13	0b RW	**RESERVED:** Write as zero.
12:0	0b RW	**PIPE_A_SECOND_FIELD_VERTICAL_SYNC_SHIFT:** This value specifies the vertical sync alignment for the start of the interlaced second field expressed in terms of the absolute pixel number relative to the horizontal active display start. This value will only be used if the PIPEACONF is programmed to an interlaced mode using vsync shift. Otherwise a legacy value of floor[htotal / 2] will be used. Typically, the interlaced second field vertical sync should start one pixel after the point halfway between successive horizontal syncs, so the value of this register should be programmed to: (horizontal sync start - floor[horizontal total / 2]) (use the actual horizontal sync start and horizontal total values and not the minus one values programmed into registers). This vertical sync shift only occurs during the interlaced second field. In all other cases the vertical sync start position is aligned with horizontal sync start.

Bit Range	Default & Access	Description
31:13	0b RW	**RESERVED:** Write as zero.
12:0	0b RW	**PIPE_B_SECOND_FIELD_VERTICAL_SYNC_SHIFT:** This value specifies the vertical sync alignment for the start of the interlaced second field expressed in terms of the absolute pixel number relative to the horizontal active display start. This value will only be used if the PIPEBCONF is programmed to an interlaced mode using vsync shift. Otherwise a legacy value of floor[htotal / 2] will be used. Typically, the interlaced second field vertical sync should start one pixel after the point halfway between successive horizontal syncs, so the value of this register should be programmed to: (horizontal sync start - floor[horizontal total / 2]) (use the actual horizontal sync start and horizontal total values and not the minus one values programmed into registers). This vertical sync shift only occurs during the interlaced second field. In all other cases the vertical sync start position is aligned with horizontal sync start.

Bit Range	Default & Access	Description
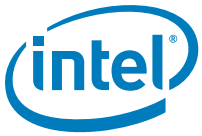
7	0b RO	**RESERVED_AS_PER_VGA_SPECIFICATION:** Read as 0s.
6	0b RO	**RESERVED:** Read as 0.



Bit Range	Default & Access	Description
5:4	0b RO	**VIDEO_FEEDBACK_1_0:** These are diagnostic video bits that are selected by the Color Plane Enable Register. These bits that are programmably connected to 2 of the 8 color bits sent to the palette. Bits 4 and 5 of the Color Plane Enable Register (AR12) selects which two of the 8 possible color bits become connected to these 2 bits of this register. The current software normally does not use these 2 bits. They exist for EGA compatibility.
3	0b RO	**VER_TI_CAL_RETRACE_VIDEO:** 0 = VSYNC inactive (Indicates that a vertical retrace interval is not taking place). 1 = VSYNC active (Indicates that a vertical retrace interval is taking place). Note: VGA pixel generation is not locked to the display output but is loosely coupled. A VSYNC indication may not occur during the actual VSYNC going to the display but during the VSYNC that is generated as part of the VGA pixel generation. The exact relationship will vary with the VGA display operational mode. This status bit will remain active when the VGA is disabled and the device is running in high resolution modes (non-VGA) to allow for applications that (now it is incorrect) use these status registers bits. In this case, the status will come from the pipe that the VGA is assigned to. Bits 4 and 5 of the Vertical Retrace End Register (CR11) previously could program this bit to generate an interrupt at the start of the vertical retrace interval. This ability to generate interrupts at the start of the vertical retrace interval is a feature that is largely unused by legacy software. Interrupts are not supported through the VGA register bits.
2:1	0b RO	**RESERVED_1:** Read as 0s.
0	0b RO	**DIS_PLAY_ENA_BLE_OUTPUT:** Display Enable is a status bit (bit 0) in VGA Input Status Register 1 that indicates when either a horizontal retrace interval or a vertical retrace interval is taking place. This was used with the IBM* EGA graphics system (and the ones that preceded it, including MDA and CGA). In those cases, it was important to check the status of this bit to ensure that one or the other retrace intervals was taking place before reading from or writing to the frame buffer. In these earlier systems, reading from or writing to frame buffer at times outside the retrace intervals meant that the CRT controller would be denied access to the frame buffer. This resulted in either snow or a flickering display. This bit provides compatibility with software designed for those early graphics controllers. This bit is currently used in DOS applications that access the palette to prevent the sparkle associated with read and write accesses to the palette ram with the same address on the same clock cycle. This status bit will remain active when the VGA display is disabled and the device is running in high resolution modes (non-VGA) to allow for applications that (now considered incorrect) use these status registers bits. In this case, the status will come from the pipe that the VGA is assigned to. When in panel fitting VGA or centered VGA operation, the meaning of these bits will not be consistent with native VGA timings. 0 = Active display data is being sent to the display. Neither a horizontal retrace interval or a vertical retrace interval is currently taking place. 1 = Either a horizontal retrace interval (horizontal blanking) or a vertical retrace interval (vertical blanking) is currently taking place.

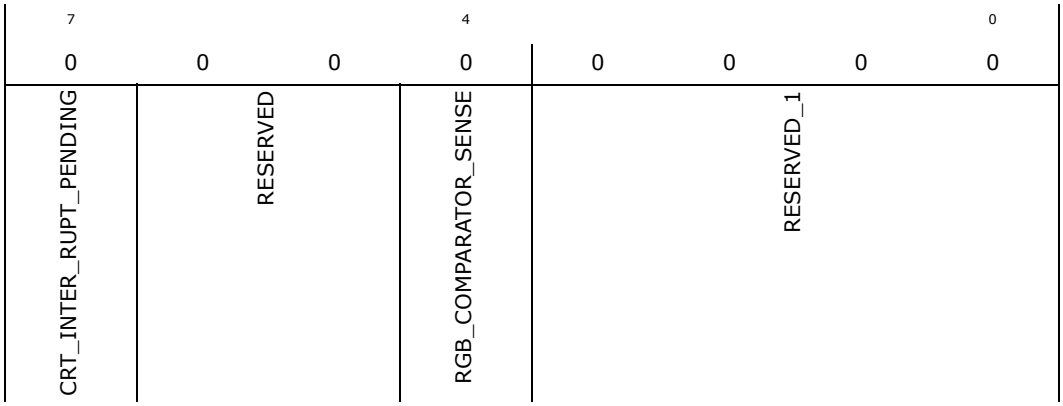
Default: 00h



Bit Range	Default & Access	Description
7	0b RO	**CRT_INTER_RUPT_PENDING:** This bit is here for EGA compatibility and will always return zero. Note that the generation of interrupts was originally enabled, through bits [4,5] of the Vertical Retrace End Register (CR11). This ability to generate interrupts at the start of the vertical retrace interval is a feature that is typically unused by DOS software and therefore is only supported through other means for use under a operating system support. 0 = CRT (vertical retrace interval) interrupt is not pending. 1 = CRT (vertical retrace interval) interrupt is pending
6:5	0b RO	**RESERVED:** Read as 0s.
4	0b RO	**RGB_COMPARATOR_SENSE:** This bit returns the state of the output of the RGB output comparator(s). Video BIOS uses this bit during POST to determine whether the display is connected and if it is a color or monochrome CRT. BIOS blanks the screen or clears the frame buffer to display only black. Next, BIOS outputs a ramp to the D-to-A converters to test for the presence of a color display by determining which code cause the comparator to switch. Finally, if the BIOS does not detect any termination resistors on Red or Blue, it tests for the presence of a display using the Green signal. The result of each such test is read via this bit. 0 = Below threshold 1 = Above threshold

In these earlier systems, reading from or writing to frame buffer at times outside the retrace intervals meant that the CRT controller would be denied access to the frame buffer. This resulted in either snow or a flickering display. This bit provides compatibility with software designed for those early graphics controllers. This bit is currently used in DOS applications that access the palette to prevent the sparkle associated with read and write accesses to the palette ram with the same address on the same clock cycle. This status bit will remain active when the VGA display is disabled and the device is running in high resolution modes (non-VGA) to allow for applications that (now considered incorrect) use these status registers bits. In this case, the status will come from the pipe that the VGA is assigned to. When in panel fitting VGA or centered VGA operation, the meaning of these bits will not be consistent with native VGA timings. 0 = Active display data is being sent to the display. Neither a horizontal retrace interval or a vertical retrace interval is currently taking place. 1 = Either a horizontal retrace interval (horizontal blanking) or a vertical retrace interval (vertical blanking) is currently taking place.

3.3.5 GTTMMADR_LSB—Offset 10h

Gfx Memory Mapped Address Range. This is the base address for all memory mapped registers and GTT table. SOXi Context Save/Restore : Yes This register requests allocation for the combined Graphics Translation Table Modification Range and Memory Mapped Range. The range requires 4 MB combined for MMIO and Global GTT aperture, with 512K of that used by MMIO and 2MB used by GTT. GTTADR will begin at (GTTMMADR + 2 MB) while the MMIO base address will be the same as GTTMMADR. For the Global GTT, this range is defined as a memory BAR in graphics device config space. It is an alias into which software is required to write Page Table Entry values (PTEs). Software may read PTE values from the global Graphics Translation Table (GTT). PTEs cannot be written directly into the global GTT memory area. The allocation is for 4MB and the base address is defined by bits [35:22].

Access Method

Type: PCI Configuration Register (Size: 32 bits)

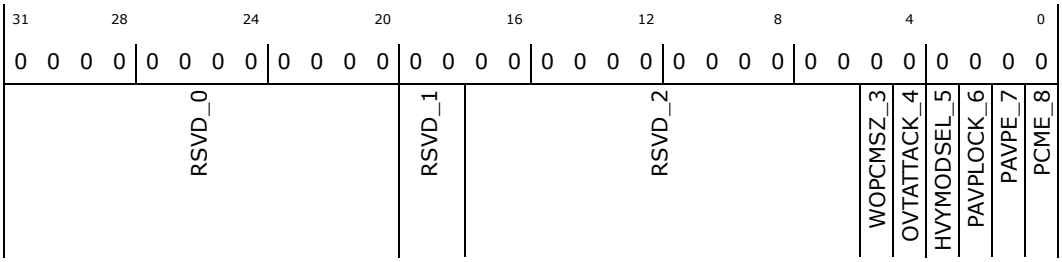
PAVPC: [B:0, D:2, F:0] + 74h

Power Well: Core

Default: 00000000h



Bit Range	Default & Access	Description
31:20	000h RO	**RSVD (RSVD_0):** Reserved. This field is used to set the base of Protected Content Memory. This corresponds to bits 31:20 of the system memory address range, giving a 1MB granularity. This value MUST be at least 1MB above the base and below the top of stolen memory. This register is locked (becomes read-only) when PAVPLOCK = 1b.
19:18	00b RO	**RSVD (RSVD_1):** Reserved. Note : IVB provided 256KB granularity, so these 2 bits were RW to support that size option. However, VV will only support 1MB so Gunit will tie bits 19:18 to '00'.
17:6	000h RO	**RSVD (RSVD_2):** Reserved
5	0b RO	**WOPCMSZ (WOPCMSZ_3):** 0b ? 1MB Note : IVB had this as a RW bit with value '1' indicating size 256KB support. Since VV only supports 1MB size, this register is RO for VV. These are the only sizes supported for IVB. The IVB is going to run PAVP3 Mode Serpent applications using per-App selection. Therefore, the size chosen should always be 1MB configuration even if Lite mode is chosen using PAVPC register (bit_3 = 0) for PAVP2 Mode Applications. This is because CB^2 code needs to be always loaded, since an App. Which opts for per-App Serpent mode will also execute the CB^2 code). The driver may consider it a BIOS programming error, if PAVPC Serpent Mode is selected with only 256KB of WOPCM size. However PAVPC Lite Mode with 1M WOPCM size is acceptable and not an error, as this may involve per-App selected Serpent Mode.

Bit Range	Default & Access	Description
4	0b RW/L	**OVTATTACK (OVTATTACK_4):** Override of Unsolicited Connection State Attack and Terminate. 0b Disable Override. Attack Terminate allowed. 1b Enable Override. Attack Terminate disallowed. This register bit is locked (becomes read-only) when PAVPLOCK = 1b
3	0b RW/L	**HVYMODSEL (HVYMODSEL_5):** In IVB, this bit is a care only for PAVP2 mode of operation (and a chicken bit is also set). For IVB PAVP2 mode: 0 : Lite Mode (Non-Serpent Mode) 1: Serpent Mode For PAVP3 mode of operation, this bit_3 is a care, only if the per-App Memory Config is disabled due to the clearing of an additional Chicken bit_9 in IVB Crypto Function Control_1 Reg (@ address 0x320F0h). For chicken bit enabled IVB PAVP3 mode, this one type boot time programming has been replaced by per-Media App. Programming (through the Media Crypto Copy command). Note that IVB PAVP2 or PAVP3 Mode selection is done by programming bit_8 of MFX_MODE ? Video Mode Register. (Note again, that when in PAVP3 Mode, the per-App Memory Config. (Serpent/Lite) feature for enabling, requires the further setting of a global one time chicken bit to be set (bit_9 = ?1/ mask_bit_25 = ?1) in the IVB Crypto Function Control_1 Register @ address 0x320F0h).
2	0b RW/L	**PAVPLOCK (PAVPLOCK_6):** This bit will lock all writeable contents in this register when set(including itself).Only a hw reset can unlock the register again. This Lock bit if PAVP is enabled (PAVPE = 1)
1	0b RW/L	**PAVPE (PAVPE_7):** 0: PAVP functionality is disabled. 1: enabled. This register is locked when PAVPLOCK=1
0	0b RW/L	**PCME (PCME_8):** PCME = Protected Content Memory Enable This field enables Protected Content Memory within Graphics Stolen Memory. This memory is the same as the WOPCM area. The size of the WOPCM area is defined by bit_5 of this register. WOPCM is the only remaining flavor of range protected memory. 0: WOPCM protection disabled. 1 : WOPCM protection enabled. This bit must be programmed to 1 when PAVP is enabled. With per-App Memory configuration support in IVB, the range check for the WOPCM memory area should always happen when this bit is set, irrespective of Lite or AES mode programming, or PAVP2 or PAVP3 Mode programming.

3.3.28 SWSMISCI—Offset E0h

Software SMI or SCI.To generate a SW SMI event, software should program bit 15:0 and trigger SMI. Note : ILK/SNB/IVB had SCI and SMI separated (E0 and E8) As long as there is the potential that DVO port legacy drivers exist which expect this register at this address, this must be reserved for this register. The SCI mechanism for driver / BIOS communication. SMI is a system wide lock interrupt (halts the all the cores) as opposed to SCI. Vista and Win7 recommend to use the SCI. The SMI is slowly being phased out. This register serves 2 purposes: 1) Support selection of SMI or SCI event source (SMISCISEL - bit15) 2) Event trigger (bit 0). To generate a SW SCI event, software (System BIOS/Graphics driver) should program bit 15 (SMISCISEL) to 1. This is typically programmed once (assuming SMIs are never triggered). On a ?0? to ?1? subsequent transition in bit 0 of this register (caused by a software write operation), GMCH sends a single SCI message. The SCI will set the DMISCI bit in its TCO1_STS register and TCOSCI_STS bit in its GPE0 register upon receiving this message from DMI. Once written as 1, software must write a ?0? to this bit to clear it, and all other write transitions (1-)0, 0-)0, 1-)1) or if bit 15 is ?0? will not cause GMCH to send SCI message to DMI link. To generate a SW SMI event, software should program bit 15 to 0 and trigger an SMI.

3.4.1 CRCCTRLREDB—Offset 61050h

Pipe B CRC Color Control Register (Red)

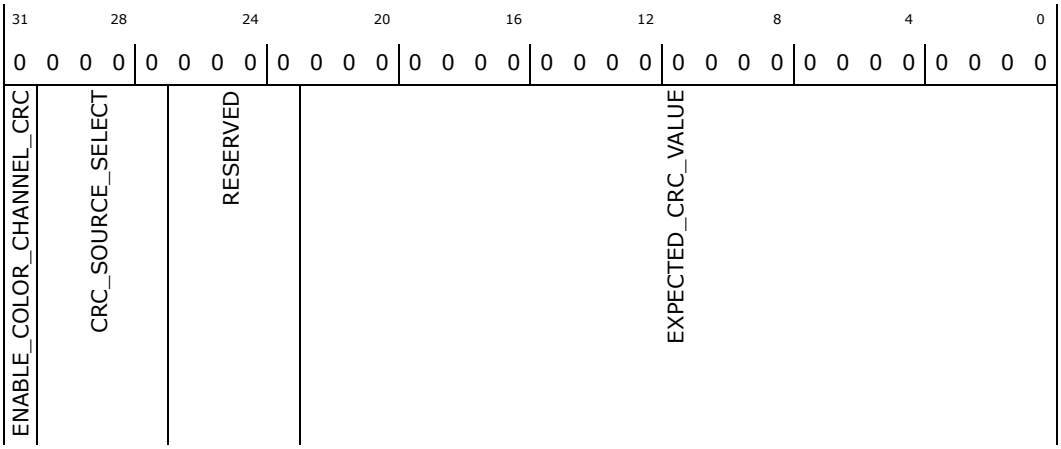
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CRCCTRLREDB: [GTTMMADR_LSB + 2BF20h] + 61050h

GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)
GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31	0b RW	**ENABLE_COLOR_CHANNEL_CRC:** After being enabled for the first time, you need to wait for two VBLANK events for a valid CRC result. After that, a CRC will be generated each frame. 0 = CRC Calculations are disabled 1 = CRC Calculations are enabled
30:27	0b RW	**CRC_SOURCE_SELECT:** These bits select the source of the data to put into the CRC logic. 0000: Pipe B (Not available when DisplayPort or TV is enabled on this pipe) [DevVLVP] 0001: sDVOB/HDMIB (30 bit format. Only select when HDMIB is set to pipe B) [DevVLVP] 0010: sDVOC/HDMIC (30 bit format. Only select when HDMIC is set to pipe B) [DevVLVP] 0011: DisplayPort D (40 bit format) [DevCTG] 0100: TV Encoder outputs (30 bit format) 0101: TV filter outputs (30 bit format) 0110: DisplayPort B (40 bit format) [DevCTG, DevCDV, DevVLVP] 0111: DisplayPort C (40 bit format) [DevCTG, DevCDV, DevVLVP] 1000: Audio DP (Audio for DisplayPort (pcdclk). Only select when Audio is on DisplayPort on Pipe B) [DevVLVP] 1001: Audio HDMI (Audio for HDMI (dotclock) Only select when Audio is on HDMI on Pipe B) Others: Reserved
26:23	0b RW	**RESERVED:** Write as zero
22:0	0b RW	**EXPECTED_CRC_VALUE:** Expected CRC Value for the Color Channel. This is the value used to generate the CRC error status and interrupt. Resultant CRC values are compared to this register after the completion of a CRC calculation. The status bit is in the PIPEBSTAT register.

15:11	0b RW	**DPLLB_POWER_DOWN_DELAY:** programmable delay from main link powerdown to DPLLB powerdown. The delay is in number of cdclk clocks.
10	0b RW	**DOUBLE_FRAMES_IN_PSR_ACTIVE_ENTRY:** . If asserted, HW will send two frames with same SDP active setting when entry PSR active state. This bit is set if the vertical blanking time is less than 330us.
9	0b RW	**SOURCE_TRANSMITTER_STATE_IN_PSR_ACTIVE:** . If asserted, HW will keep transmitter active during PSR active state and sends only idle symbols. If deasserted, HW will turn off transmitter during PSR active state. Display driver will keep this bit consistent with Source transmitter state in PSR active bit in DPCD register of the sink.

Bit Range	Default & Access	Description
8	0b RW	**PSR_ACTIVE_ENTRY:** This bit is only valid in PSR_mode is SW timer mode. If it is asserted, HW will transition into PSR_active state. If it is deasserted, HW will transition to PSR_inactive state. SW should not set or clear this bit more than once within one vblank period.
7	0b RW	**PSR_SINGLE_FRAME_UPDATE:** In PSR SW or HW mode, SW set this bit before writing registers for a flip. After HW finishes single frame update, it goes back to PSR active ? no RFB state. SW driver may send new single frame update request. Programming note: Reading this bit is updated at the next vblank. Writing this bit to 1 will cause PSR FSM to perform single frame update automatically, no vblank is required. When single frame update is done, it will automatically go back to PSR active ? no RFB update. 61094[2:0] = 3b011.
6:5	0b RW	**RESERVED_1:** Reserved.
4:2	0b RW	**PSR_MODE:** b011-111: reserved. b010: PSR with HW timer. HW timer decides PSR active entry point. PSR active state exits upon MMIO write registers that may change the frame buffer. b001: PSR with SW timer. In this mode, SW will keep track of idle frames and buffer modification in the driver and explicitly specify the entry and exit PSR active state point. b000: PSR manual (debug) mode. All of PSR state transitions and SDP content is managed by SW driver. SW is responsible to change SDP content for every frame with appropriate values to keep PSR panel in synchronized states.
1	0b RW	**PSR_RESET:** If assert all PSR functions are reset back to PSR inactive state. When it needs to resynchronize source and sync, SW writes 0x2 to DPCD register 600h and to this bit to get system back to PSR active states. This bit is self clear.
0	0b RW	**PSR_ENABLE:** Panel Self-refresh is enabled. When it is asserted PSR is enabled and operate in one of the mode that specified by PSR mode.

Bit Range	Default & Access	Description
31	0b RW	**SDVO_HDMIB_ENABLE_DIGITAL_DISPLAY_PORT_B_ENABLE:** Disabling this port will put it in its lowest power state. Port enable takes place on the Vblank after being written. Both this bit and bit 6 of this register must be enabled to send audio over this port. This port must not be enabled simultaneously with DisplayPort B. [DevIBX] When disabling the port, software must temporarily enable the port with transcoder select (bit #30) cleared to 0 after disabling the port. This is workaround for hardware issue where the transcoder select set to 1 will prevent DisplayPortB from being enabled on transcoder A. [DevIBX] Software must write this bit twice when enabling the port (setting to 1) as a workaround for hardware issue that may result in first write getting masked. [DevIBX] Toggle this bit off then on at the end of mode set sequence when enabling HDMI 12-bit per color with pixel repeat 1 = Enable. This bit enables the Digital Display Port B interface for HDMI or SDVO modes. 0 = Disable and tristates the Digital Display Port B interface for HDMI or SDVO modes.
30	0b RW	**PIPE_SELECT:** This bit determines from which display pipe the source data will originate. This only applies to devices with dual display pipes. Pipe selection takes place on the Vblank after being written 0 = Pipe A 1 = Pipe B
29	0b RW	**RESERVED:** [DevCDV]: [DevCTG, DevBW, DevCL, DevBLC] Stall Select: This bit selects stall for external scaling functionality only on SDVO. Programming notes: It is only valid to have a single stall indication to a particular pipe. In cases where two ports are being driven from a single pipe, one of the ports must set this bit to 0. Only sDVOB or sDVOC can select the stall function, as only a single stall input is available between the two interfaces. Set the stall input to unused before programming the external device creating the stall. 0 = Stall input signal is unused on this port 1 = Stall input signal is used to stall the pipe attached to this port
28:26	0b RW	**COLOR_FORMAT:** This field selects the number of bits per color sent to a receiver device connected to this port. Color format takes place on the Vblank after being written. Color format change must be done as a part of mode set since different color depths require different pixel clock settings. Selecting a pixel color depth higher or lower than the pixel color depth of the frame buffer results in dithering the output stream. 000 = 8 bits per color (Default, x3 mode) 001 = RESERVED for 10 bits per color 010 = RESERVED for 6 bits per color 011 = RESERVED 1xx = RESERVED
25:19	0b RW	**RESERVED_1:** Reserved.

12	0b RW	**RESERVED_5:** [DevCDV, DevVLVP]: [DevBW, DevCL, DevBLC, DevCDV] Scrambling enable: This bit enables scrambling for UDI-related modes using ANSI 8b/10b or TMDS encoding. Scrambling is reset at the beginning of horizontal sync. 0 = Scrambling disabled (Default) 1 = Scrambling enabled
11:10	0b RW	**ENCODING:** [DevCDV, DevCTG, DevCL] These bits select among encoding types. It is set as part of the display detection process. Control codes for ANSI 8b/10b and TMDS encoding must be programmed using these bits. Please note that ANSI 8b/10b and TMDS encoding can only be enabled on one port at a time, as only one HPD pin is available for use between ports B and C. 00 = Reserved 01 = Reserved 10 = TMDS encoding ([DevCL, DevCTG, DevCDV, DevVLVP] external link and HDMI only) See the HDMI specification for control codes. In this mode, the external HPD pin is used to generate hotplug. In fixed frequency mode, start of fill and end of fill values for TMDS must be programmed using register 6114C. 11 = Reserved
9	0b RW	**NULL_PACKETS_ENABLED_DURING_VSYNC:** This bit enables a null packet (32 bytes of a value of 0) to be sent when Vsync=1 on this port, required for HDMI operation. It also enables preambles and guardbands prior to the null packets, in accordance with the HDMI specification. It is only valid for modes that use TMDS encoding. 0 = Disable null infoframe packets when Vsync=1 on this port. (Default) 1 = Enable null infoframe packets when Vsync=1 on this port.

Blank# is used to generate the DE output (used in all cases except when the external scaler is used in a DVI panel, over SDVO) . 0 = Border to the sDVOB encoder is disabled. DE (Display Enable) is used
6	0b RW	**AUDIO_OUTPUT_ENABLE:** [DevCDV, DevCTG, DevCL] This bit directs audio to this port. When enabled and audio data is available, the audio data will be combined with the video data and sent over this port. The audio unit uses the status of this bit to indicate presence of the HDMI output to the audio driver. 0 = (Default) No audio output on this port 1 = Enable audio on this port

Bit Range	Default & Access	Description
5	0b RW	**HDCP_PORT_SELECT:** [DevCDV, DevCTG, DevCL] This bit directs HDCP to this port. When enabled, the information sent on this port will be encrypted using HDCP. 4:3	11b RW	**SYNC_POLARITY:** Please note that sync polarity does not apply to ANSI coding. Indicates the polarity of Hsync and Vsync. Inverted polarity is transmitted as SYNC-BLANK-SYNC and standard polarity is transmitted as BLANK-SYNC-BLANK. For example, if Vsync is not inverted and Hsync is inverted, an Hsync period transmitted during Vsync would be transmitted as BLANK+VS+HS BLANK+VS BLANK+VS+HS. Please note that in native VGA modes, these bits have no effect. In native VGA modes, sync polarity is determined by VRshr3c2d76b[7:6], the VGA polarity bits in VGA control. 00 = VS and HS are active low (inverted) 01 = VS is active low (inverted), HS is active high 10 = VS is active high, HS is active low (inverted) 11 = (Default) VS and HS are active high

3.4.28 HDMIC—Offset 61160h

Digital Display Port C Register HDMIC port control (dprrega.v sdvo_cQ)

Access Method

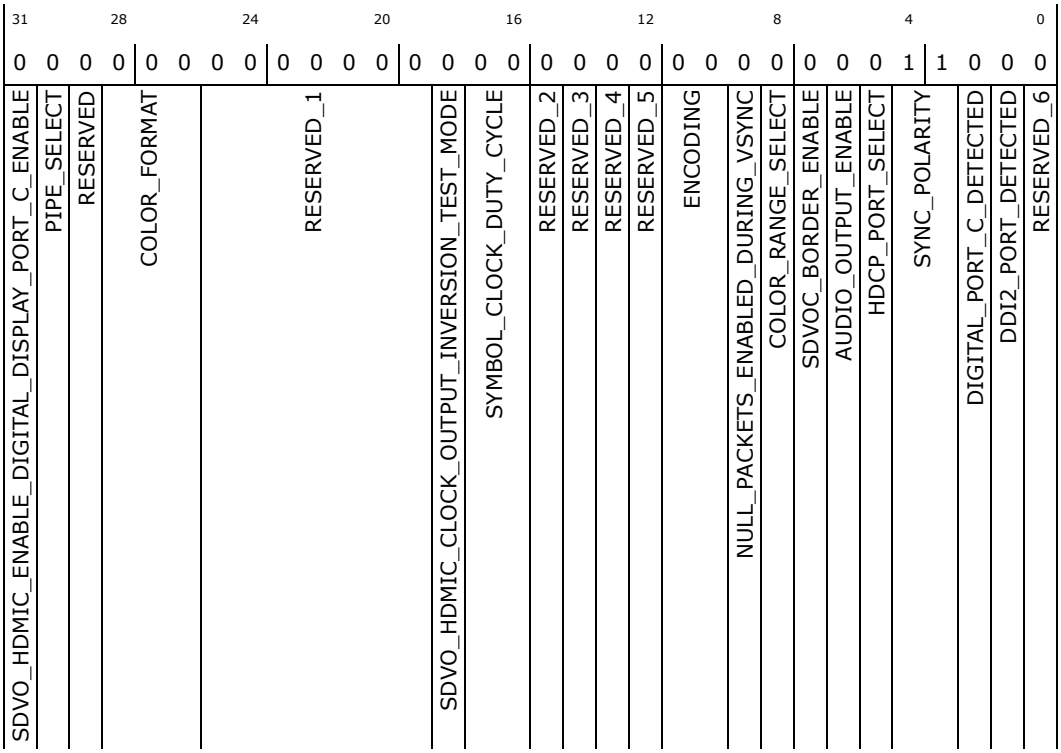
Type: Memory Mapped I/O Register (Size: 32 bits)

HDMIC: [GTTMMADR_LSB + 2BF20h] + 61160h

GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)

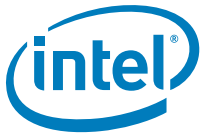
GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

Default: 00000018h



Bit Range	Default & Access	Description
31	0b RW	**SDVO_HDMIC_ENABLE_DIGITAL_DISPLAY_PORT_C_ENABLE:** Disabling this port will put it in its lowest power state. Port enable takes place on the Vblank after being written. Both this bit and bit 6 of this register must be enabled to send audio over this port in HDMI. This port must not be enabled simultaneously with DisplayPort C. [DevIBX] When disabling the port, software must temporarily enable the port with transcoder select (bit #30) cleared to 0 after disabling the port. This is workaround for hardware issue where the transcoder select set to 1 will prevent DPC from being enabled on transcoder A. [DevIBX] Software must write this bit twice when enabling the port (setting to 1) as a workaround for hardware issue that may result in first write getting masked. [DevIBX] Toggle this bit off then on at the end of mode set sequence when enabling HDMI 12-bit per color with pixel repeat. 1 = Enable. This bit enables the Digital Display Port C interface for HDMI or DVI modes. 0 = Disable and tristates the Digital Display Port C interface for HDMI or DVI modes.
30	0b RW	**PIPE_SELECT:** This bit determines from which display pipe the source data will originate. This only applies to devices with dual display pipes. Pipe selection takes place on the Vblank after being written 0 = Pipe A 1 = Pipe B

Bit Range	Default & Access	Description
29	0b RW	**RESERVED:** [DevCDV]: stall Select: This bit selects stall for external scaling functionality only on SDVO. Programming notes: It is only valid to have a single stall indication to a particular pipe. In cases where two ports are being driven from a single pipe, one of the ports must set this bit to 0. Only sDVOB or sDVOC can select the stall function, as only a single stall input is available between the two interfaces. Set the stall input to unused before programming the external device creating the stall. 0 = Stall input signal is unused on this port 1 = Stall input signal is used to stall the pipe attached to this port
28:26	0b RW	**COLOR_FORMAT:** This field selects the number of bits per color sent to a receiver device connected to this port. Color format takes place on the Vblank after being written. Color format change must be done as a part of mode set since different color depths require different pixel clock settings. Selecting a pixel color depth higher or lower than the pixel color depth of the frame buffer results in dithering the output stream. 000 = 8 bits per color (Default) 001 = RESERVED for 10 bits per color 010 = RESERVED for 6 bits per color 011 = RESERVED 1xx = RESERVED
25:19	0b RW	**RESERVED_1:** Reserved.
18	0b RW	**SDVO_HDMIC_CLOCK_OUTPUT_INVERSION_TEST_MODE:** Please note that this applies to all modes and is instantly updated. 1 = sDVO/HDMIB Clock output is inverted 0 = sDVO/HDMIB Clock output is NOT inverted (DEFAULT)
17:16	0b RW	**SYMBOL_CLOCK_DUTY_CYCLE:** These bits control the output clock duty cycle to enable EMI mitigation on the external HDMI link. 10/90 cycle has been measured to have ~13dB EMI improvement over a 50/50 duty cycle. 00 = (Default) 50/50 duty cycle: Clock output is 0000011111 01 = 10/90 duty cycle: Clock output is 0111111111 followed by 0000000001 ([DevCL, DevCTG, DevCDV] HDMI only) 10 = 20/80 duty cycle: Clock output is 0011111111 followed by 0000000011 ([DevCL, DevCTG, DevCDV] HDMI only) 11 = Reserved
15	0b RW	**RESERVED_2:** [DevCTG, DevCDV, DevVLVP] Port Lane Reversal: This bit reverses the order of the 4 lanes within the port. Port lane reversal takes place on the Vblank after being written. It is an OEM configurable feature. 0 = (Default) Not reversed 1 = Reversed
14	0b RW	**RESERVED_3:** Reserved.
13	0b RW	**RESERVED_4:** [DevCTG, DevCDV, DevVLVP] Clock Output Disable: This bit disables the clock output on the digital output port. For 8b/10b modes the clock output should be disabled. 0 = (Default) Clock output enabled 1 = Clock output disabled ([DevCL] only)
12	0b RW	**RESERVED_5:** [DevCTG, DevCDV, DevVLVP]: Scrambling enable: This bit enables scrambling for UDI-related modes using ANSI 8b/10b or TMDS encoding. It is not used with SDVO encoding. Software must set this bit appropriately when enabling the port. Scrambling is reset at the beginning of horizontal sync. 0 Scrambling disabled (Default) 1 = Scrambling enabled ([DevCL] only)



Bit Range	Default & Access	Description
11:10	0b RW	**ENCODING:** These bits select among encoding types. It is set as part of the display detection process. Control codes for ANSI 8b/10b and TMDS encoding must be programmed using these bits. Please note that ANSI 8b/10b and TMDS encoding can only be enabled on one port at a time, as only one HPD pin is available for use between ports B and C. 00 = Reserved 01 = Reserved 10 = TMDS encoding ([DevCL, DevCTG, DevCDV, DevVLVP] external link and HDMI only) See the HDMI specification for control codes. In this mode, the external HPD pin is used to generate hotplug. In fixed frequency mode, start of fill and end of fill values for TMDS must be programmed using register 6114C. 11 = Reserved
9	0b RW	**NULL_PACKETS_ENABLED_DURING_VSYNC:** This bit enables a null packet (32 bytes of a value of 0) to be sent when Vsync=1 on this port, required for HDMI operation. It also enables preambles and guardbands prior to the null packets, in accordance with the HDMI specification. It is only valid for modes that use TMDS encoding. 0 = Disable null infoframe packets when Vsync=1 on this port. (Default) 1 = Enable null infoframe packets when Vsync=1 on this port.
8	0b RW	**COLOR_RANGE_SELECT:** This bit is used to select the color range of RBG outputs in HDMI mode. It is only valid when using TMDS encoding and 8 bit per color mode. 0 = Apply full 0-255 color range to the output (Default) 1 = Apply 16-235 color range to the output ([DevCL and DevCTG] only)
7	0b RW	**SDVOC_BORDER_ENABLE:** This bit determines if the border data from native VGA or the timing generator is to be considered valid pixel data at the external component. 1 = Border to the sDVOC encoder is enabled. Blank# is used to generate the DE output (used in all cases except when the external scaler is used in a DVI panel, over SDVO) . 0 = Border to the sDVOC encoder is disabled. DE (Display Enable) is used
6	0b RW	**AUDIO_OUTPUT_ENABLE:** ([DevCL, DevCTG, DevCDV]): This bit directs audio to this port. When enabled and audio data is available, the audio data will be combined with the video data and sent over this port. The audio unit uses the status of this bit to indicate presence of the HDMI output to the audio driver. 0 = (Default) No audio output on this port 1 = Enable audio on this port ([DevCL, DevCTG, DevCDV] only)
5	0b RW	**HDCP_PORT_SELECT:** This bit directs HDCP to this port. When enabled, the information sent on this port will be encrypted using HDCP. Please note that this bit does not enable encryption on its own, but must be used in conjunction with HDCP registers. 0 = (Default) No HDCP encryption on this port 1 = Enable HDCP on this port ([DevCL, DevCTG, DevCDV] only)
4:3	11b RW	**SYNC_POLARITY:** Please note that sync polarity does not apply to ANSI coding. Indicates the polarity of Hsync and Vsync. Inverted polarity is transmitted as SYNC-BLANK-SYNC and standard polarity is transmitted as BLANK-SYNC-BLANK. For example, if Vsync is not inverted and Hsync is inverted, an Hsync period transmitted during Vsync would be transmitted as BLANK+VS+HS BLANK+VS BLANK+VS+HS. Please note that in native VGA modes, these bits have no effect. In native VGA modes, sync polarity is determined by VRshr3c2d76b[7:6], the VGA polarity bits in VGA control. 00 = VS and HS are active low (inverted) 01 = VS is active low (inverted), HS is active high 10 = VS is active high, HS is active low (inverted) 11 = (Default) VS and HS are active high

When it is desired to divide by N, the actual value to be programmed is (N/2)-1. The value should be (100*RefinMHz/2)-1. The default value assumes the default value for the display core clock that is for [DevCL and DevCTG] a 200MHz reference value. The following are examples for other memory speeds. Display Core Frequency Value of Field 233MHz 2D81h 200MHz 270Fh 133MHz 19F9h
7:5	0b RW	**RESERVED:** Reserved.
4:0	00100b RW	**POWER_CYCLE_DELAY:** Programmable value of time panel must remain in a powered down state after powering down. For devices coming out of reset, the default values will define how much time must pass before a power on sequence can be started. This field uses the .1 S time base unit from the divider. If the panel power on sequence is attempted during this delay, the power on sequence will commence once the power cycle delay is complete. Writing a value of 0 selects no delay or is used to abort the delay if it is active. During the initial power up reset, a D3 cold power cycle, or a user instigated system reset, the timer will be set to the default value and the count down will begin after the de-assertion of reset. Writing this field to a zero while the count is active will abort this portion of the sequence. This corresponds to the T4 of the SPWG specification. Note: Even if the panel is not enabled, the T4 count happens after reset. This register needs to be programmed to a +1 value. For instance for meeting the SPWG specification of 400mS, program 5 to achieve at least 400mS delay prior to powerup.

Bit Range	Default & Access	Description
31:8	000000000010011100001111b RW	**REFERENCE_DIVIDER:** This field provides the value of the divider used for the creation of the panel timer reference clock. The output of the divider is used as the fastest of the three time bases (100us) for all other timers. The other time bases are divided from this frequency. The value of zero should not be used. When it is desired to divide by N, the actual value to be programmed is (N/2)-1. The value should be (100*RefinMHz/2)-1. The default value assumes the default value for the display core clock that is for [DevCL and DevCTG] a 200MHz reference value. The following are examples for other memory speeds. Display Core Frequency Value of Field 233MHz 2D81h 200MHz 270Fh 133MHz 19F9h
7:5	0b RW	**RESERVED:** Reserved.

Bit Range	Default & Access	Description
4:0	00100b RW	**POWER_CYCLE_DELAY:** Programmable value of time panel must remain in a powered down state after powering down. For devices coming out of reset, the default values will define how much time must pass before a power on sequence can be started. This field uses the .1 S time base unit from the divider. If the panel power on sequence is attempted during this delay, the power on sequence will commence once the power cycle delay is complete. Writing a value of 0 selects no delay or is used to abort the delay if it is active. During the initial power up reset, a D3 cold power cycle, or a user instigated system reset, the timer will be set to the default value and the count down will begin after the de-assertion of reset. Writing this field to a zero while the count is active will abort this portion of the sequence. This corresponds to the T4 of the SPWG specification. Note: Even if the panel is not enabled, the T4 count happens after reset. This register needs to be programmed to a +1 value. For instance for meeting the SPWG specification of 400mS, program 5 to achieve at least 400mS delay prior to powerup.

Bit Range	Default & Access	Description
31	0b RW	**SEND_BUSY:** Setting this bit to a one initiates the transaction, when read this bit will be a 1 until the transmission completes. The transaction is completed when the response is received or when a time out occurs. Do not write a 1 again until transaction completes. Writes of 0 will be ignored.
30	0b RW/1C	**DONE:** A sticky bit that indicates the transaction has completed. SW must write a 1 to this bit to clear the event. AccessType: One to Clear
29	0b RW	**INTERRUPT_ON_DONE:** Enable an interrupt in the hotplug status register when the transaction completes or times out.
28	0b RW/1C	**TIME_OUT_ERROR:** A sticky bit that indicates the transaction has timed out. SW must write a 1 to this bit to clear the event. AccessType: One to Clear
27:26	0b RW	**TIME_OUT_TIMER_VALUE:** 00: 400us (default) 01: 600us 10: 800us 11: 1600us The time count depends on the 2X bit clock divider (bits 10:0) being programmed for 2MHz.
25	0b RW/1C	**RECEIVE_ERROR:** A sticky bit that indicates that the data received was corrupted, not in multiples of a full byte, or more than 20 bytes. SW must write a 1 to this bit to clear the event. AccessType: One to Clear

Bit Range	Default & Access	Description
24:20	0b RW	**MESSAGE_SIZE:** This field is used to indicate the total number bytes to transmit (including the header). It also indicates the number of bytes received in a transaction (including the header). This field is valid only only when the done bit is set and timeout or receive error has not occurred. Sync/ Stop are not part of the message or the message size. Reads of this field will give the response message size. The read value will not be valid while Busy bit 31 is asserted. Message sizes of 0 or)20 are not allowed.
19:16	0101b RW	**PRECHARGE_TIME:** Used to determine the precharge time for the Aux Channel drivers. The value is the number of microseconds times 2. This depends on the 2X bit clock divider (bits 10:0) being programmed for 2MHz. Default is 5 decimal which gives 10us of precharge. Example: For 12us precharge, program 6 (12us/2us).
15	0b RW	**AUX_AKSV_BUFFER_SELECT:** This bit selects whether some of the data to be written over Display Port AUX comes from the Aksv buffer for HDCP authentication, or all from the AUX Data registers. Set this bit before initiating a transaction to write Aksv to the Display Port sink. All AUX protocol must be followed and Message Size set to 9 bytes. The first DWord transmitted will be from the AUX Data Register 1 for the header, then the DP_AUX_CH_AKSV_HI, then the last byte from DP_AUX_CH_AKSV_LO. The sink response is read back as usual from the AUX Data registers. More than one AUX channel can select to use the Aksv buffer simultaneously. 0 (Default) Use AUX Data registers for regular data transmission 1 Use Aksv Buffer for part of the data transmission.
14	0b RW	**INVERT_MANCHESTER_TEST_MODE:** 1 = Manchester code rising edge mid-clk signifies one (test mode) 0 = Manchester code rising edge mid-clk signifies zero (default)
13	0b RW	**SYNC_ONLY_CLOCK_RECOVERY_TEST_MODE:** 1 = Only recover clock during sync pattern (test mode) 0 = Recover clock during sync pattern and data phase (default)
12	0b RW	**DISABLE_DE_GLITCH_TEST_MODE:** 1 = Disable serial input de-glitch logic (test mode) 0 = Enable serial input de-glitch logic (default)
11	0b RW	**DOUBLE_PRECHARGE_TEST_MODE:** 1 = Precharge time is doubled 0 = Precharge time is as programmed
10:0	0b RW	**_2X_BIT_CLOCK_DIVIDER:** Used to determine the 2X bit clock the Aux Channel logic runs on. This value divides the input clock frequency down to 2X bit clock rate. The 2X bit clock rate is ideally 2MHz (0.5us). [DevCTG-A] the input clock is cdclk. [DevCTG-B, DevCDV] the input clock is hrawclk (200MHz) Example: For 300MHz input clock and desired 2MHz 2X bit clock, program 150 (300MHz/2MHz).

DPB-AUX and DPC-AUX are interconnected through I/O buffer loopbacks. DPB-AUX is programmed as source to output a 20 byte test pattern. DPC-AUX is programmed as sink to receive the test pattern and reply with a different 20 byte test pattern. Test pattern 1 = 0xA55CC33E E770080C 0E0F0F8F CFEFF81C 3E77E3C8 Test pattern 2 = 0X183C7EE7 C381FF7F 3F1F0F07 030100EE 77CC33A5 Programming sequence: 1. Set DPB-AUX Full Test Enable to 1. 2. Program DPB_AUX_CH_DATA[1-5] with test pattern 1 to transmit as the source. 3. Program DPC_AUX_CH_DATA[1-5] with test pattern 2 to reply with as the sink. 4. Program all DPC_AUX_CH_CTL fields and set Send to 1. 5. Program all DPB_AUX_CH_CTL fields and set Send to 1. Then the test will start. Results checking sequence: 1. Poll DPB_AUX_CH_CTL for Done. To pass, Done must be set within 500us. 2. Read DPB_AUX_CH_CTL register. To pass, Timeout Error and Receive Error must be 0. 3. Read DPC_AUX_CH_CTL register. To pass, Receive Error must be 0. 4. Read DPB_AUX_CH_DATA[1-5] registers. To pass, they must contain test pattern 2. 5. Read DPC_AUX_CH_DATA[1-5] registers. To pass, they must contain test pattern 1. Clear this bit to 0 after test is done to return DP-AUX to normal operation. Test must be repeated with and without lane reversal to verify DPB-AUX buffer combinations. Only enable one DP-AUX Full Test at a time. To abort a test in progress, write the AUX_CH_CTL Send bits to 0 and Full Test Enable to 0. GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

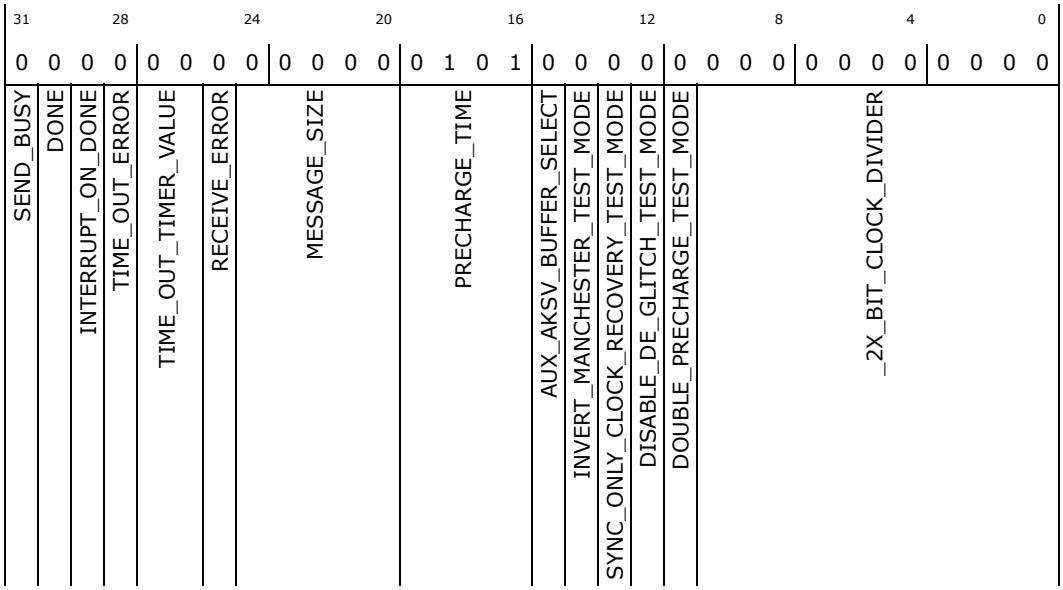
Default: 00050000h



Bit Range	Default & Access	Description
31	0b RW	**SEND_BUSY:** Setting this bit to a one initiates the transaction, when read this bit will be a 1 until the transmission completes. The transaction is completed when the response is received or when a timeout occurs. Do not write a 1 again until transaction completes. Writes of 0 will be ignored.
30	0b RW/1C	**DONE:** A sticky bit that indicates the transaction has completed. SW must write a 1 to this bit to clear the event. AccessType: One to Clear
29	0b RW	**INTERRUPT_ON_DONE:** Enable an interrupt in the hotplug status register when the transaction completes or times out.
28	0b RW/1C	**TIME_OUT_ERROR:** A sticky bit that indicates the transaction has timed out. SW must write a 1 to this bit to clear the event. AccessType: One to Clear
27:26	0b RW	**TIME_OUT_TIMER_VALUE:** 00: 400us (default) 01: 600us 10: 800us 11: 1600us The time count depends on the 2X bit clock divider (bits 10:0) being programmed for 2MHz.
25	0b RW/1C	**RECEIVE_ERROR:** A sticky bit that indicates that the data received was corrupted, not in multiples of a full byte, or more than 20 bytes. SW must write a 1 to this bit to clear the event. AccessType: One to Clear
24:20	0b RW	**MESSAGE_SIZE:** This field is used to indicate the total number bytes to transmit (including the header). It also indicates the number of bytes received in a transaction (including the header). This field is valid only only when the done bit is set and timeout or receive error has not occurred. Sync/ Stop are not part of the message or the message size. Reads of this field will give the response message size. The read value will not be valid while Busy bit 31 is asserted. Message sizes of 0 or)20 are not allowed.

Bit Range	Default & Access	Description
19:16	0101b RW	**PRECHARGE_TIME:** Used to determine the precharge time for the Aux Channel drivers. The value is the number of microseconds times 2. This depends on the 2X bit clock divider (bits 10:0) being programmed for 2MHz. Default is 5 decimal which gives 10us of precharge. Example: For 12us precharge, program 6 (12us/2us).
15	0b RW	**AUX_AKSV_BUFFER_SELECT:** This bit selects whether some of the data to be written over Display Port AUX comes from the Aksv buffer for HDCP authentication, or all from the AUX Data registers. Set this bit before initiating a transaction to write Aksv to the Display Port sink. All AUX protocol must be followed and Message Size set to 9 bytes. The first DWord transmitted will be from the AUX Data Register 1 for the header, then the DP_AUX_CH_AKSV_HI, then the last byte from DP_AUX_CH_AKSV_LO. The sink response is read back as usual from the AUX Data registers. More than one AUX channel can select to use the Aksv buffer simultaneously. 0 (Default) Use AUX Data registers for regular data transmission 1 Use Aksv Buffer for part of the data transmission.
14	0b RW	**INVERT_MANCHESTER_TEST_MODE:** 1 = Manchester code rising edge mid-clk signifies one (test mode) 0 = Manchester code rising edge mid-clk signifies zero (default)
13	0b RW	**SYNC_ONLY_CLOCK_RECOVERY_TEST_MODE:** 1 = Only recover clock during sync pattern (test mode) 0 = Recover clock during sync pattern and data phase (default)
12	0b RW	**DISABLE_DE_GLITCH_TEST_MODE:** 1 = Disable serial input de-glitch logic (test mode) 0 = Enable serial input de-glitch logic (default)
11	0b RW	**DOUBLE_PRECHARGE_TEST_MODE:** 1 = Precharge time is doubled 0 = Precharge time is as programmed
10:0	0b RW	**_2X_BIT_CLOCK_DIVIDER:** Used to determine the 2X bit clock the Aux Channel logic runs on. This value divides the input clock frequency down to 2X bit clock rate. The 2X bit clock rate is ideally 2MHz (0.5us). [DevCTG-A] the input clock is cdclk. [DevCTG-B] the input clock is hrawclk. Example: For 300MHz input clock and desired 2MHz 2X bit clock, program 150 (300MHz/ 2MHz).

Bit Range	Default & Access	Description
31	0b RW	**PIPE_A_ENABLE:** Setting this bit to the value of one, turns on pipe A. This must be done before any planes are enabled on this pipe. Changing it to a zero should only be done when all planes that are assigned to this pipe have been disabled. Turning the pipe enable bit off disables the timing generator in this pipe. Plane disable occurs after the next VBLANK event after the plane is disabled. Synchronization pulses to the display are not maintained if the timing generator is disabled. Power consumption will be at it s lowest state when disabled. A separate bit controls the DPLL enable for this pipe. Pipe timing registers should contain valid values before this bit is enabled. 0 = Disable 1 = Enable
30	0b RO	**PIPE_STATE:** This bit indicates the actual state of the pipe. Since there can be some delay between disabling the pipe and the pipe actually shutting off, this bit indicates the true current state of the pipe. 0 = Disabled 1 = Enabled AccessType: Read Only
29	0b RO	**DSI_PLL_LOCK_LOCK:** This bit indicates the clocks from DSI PLL are locked. 0 = Unlocked 1 = Locked AccessType: Read only
28:27	0b RW	**FRAME_START_DELAY:** (TEST MODE) Used to delay the frame start signal that is sent to the display planes. Normal operation uses the default 00 value and test modes can use the delayed frame start to shorten the test time. Care must be taken to insure that there are enough lines during VBLANK to support this setting. 00 = Frame Start occurs on the first HBLANK after the start of VBLANK 01 = Frame Start occurs on the second HBLANK after the start of VBLANK 10 = Frame Start occurs on the third HBLANK after the start of VBLANK 11 = Frame Start occurs on the forth HBLANK after the start of VBLANK
26	0b RW	**DISPLAY_PORT_AUDIO_ONLY_MODE:** [DevVLVP] Setting this bit to 1 indicates the DisplayPort will output audio only. 0 = DisplayPort will output Video or Video and Audio 1 = DisplayPort will output Audio only
25	0b RW	**FORCE_BORDER:** : (TEST MODE)0 = Normal Operation 1 = Color information is ignored and border color is substituted during active region
24	0b RW	**PIPE_A_GAMMA_UNIT_MODE:** This bit selects which mode the pipe gamma correction logic works in. In the palette mode, it behaves as a 3X256x8 RAM lookup. VGA and indexed mode operation should use the palette in 8-bit mode. In the 10-bit gamma mode, it will act as a piecewise linear interpolation. Other gamma units such as in the overlay or sprite are unaffected by this bit. 0 = 8-bit Palette Mode 1 = 10-bit Gamma Mode
23:21	0b RW	**INTERLACED_MODE:** These bits are used for software control of interlaced behavior. They are updated immediately if the pipe is off, or in the vertical blank after programming if pipe is enabled. 0xx = Progressive 100 = Interlaced embedded panel using programmable vertical sync shift. (2x) 101 = Interlaced using vertical sync shift. Backup option to 110 setting. (2x) 110 = Interlaced with VSYNC/HSYNC Field Indication using legacy vertical sync shift. Used for SDVO. 111 = Interlaced with Field 0 Only using legacy vertical sync shift. Not used Note: VGA display modes, sDVO line stall, and Panel fitting do not work while in interlaced modes Setting the Interlaced embedded panel mode causes hardware to automatically modify the output to match the specifications of panels that support interlaced mode.
20	0b RW	**MIPI_DISPLAY_SELF_REFRESH_MODE_FOR_MIPI_A_REFRESH:** 0 = Normal Operation, display controller generate timing and refresh display panel at refresh rate 1 = Display self-refresh mode. Display controller update frame buffer in display module on demand only

Bit Range	Default & Access	Description
19	0b RW	**DISPLAY_OVERLAY_PLANES_OFF:** This bit when set will cause all enabled Display and overlay planes that are assigned to this pipe to be disabled by overriding the current setting of the plane enable bit, at the next VBLANK. Timing signals continue as they were but the screen becomes blank. Setting the bit back to a zero will then allow the display and overlay planes to resume on the following VBLANK. 0 = Normal Operation 1 = Planes assigned to this pipe are disabled.
18	0b RW	**CURSOR_PLANES_OFF:** This bit when set will cause all enabled cursor planes that are assigned to this pipe to be disabled by overriding the current setting of the plane enable bit, at the next VBLANK. Timing signals continue as they were but the cursor(s) no longer appear on the screen. Setting the bit back to a zero will then allow the cursor planes to resume on the following VBLANK. 0 = Normal Operation 1 = Planes assigned to this pipe are disabled.
17:16	0b RW	**REFRESH_RATE_CXSR_MODE_ASSOCIATION:** These bits select how refresh rates are tied to big FIFO mode on pipe A. When they are set to anything other than 00, bits 23:21 of this register must be programmed to 0xx. Switching between 01 and 10 settings directly is not allowed. Software must program this field to 00 before switching. Software is responsible for enabling this mode only for integrated display panels that support corresponding mode. 00 Default no dynamic refresh rate change enabled. Software control only. 01 Progressive-to-progressive refresh rate change enabled and tied to big FIFO mode. Pixel clock values set in FPA0/FPA1 settings in the DPLLA control register and FPA0/FPA1 divider registers. FPA0 is tied to non-big-FIFO mode 10 Progressive-to-interlaced refresh rate change enabled and tied to big FIFO mode. Pixel clock value does not change in this case. Scaling must be disabled in this mode. Uses programmable VS shift 11 Reserved
15	0b RW	**COLOR_CORRECTION_MATRIX_ENABLE_ON_PIPE_A_1_COLOR_CORRECTION_COEFFICIENTS_ARE_ENABLED_TO_PERFORM_COLOR_CORRECTION_0_COLOR_CORRECTION_COEFFICIENTS_ARE_DISABLED_:** • 1 = Color Correction Coefficients are enabled to perform color correction • 0 = Color Correction Coefficients are disabled
14	0b RW	**DISPLAYPORT_POWER_MODE_SWITCH_DEVVLVP:** This bit selects the software controlled progressive to progressive power saving mode (software controlled DRRS). Hardware Controlled Refresh Rate Select must be disabled when enabling this. Link and data M/N 1 values are used for normal settings, M/N 2 values are used for low power settings. 0 Normal progressive refresh rate (default) 1 Low Power progressive refresh rate
13	0b RW	**COLOR_RANGE_SELECT:** [DevVLVP]: This bit is used to select the color range of RBG outputs. 0 = Apply full 0-255 color range to the output (Default) 1 = Apply 16-235 color range to the output
12	0b RW	**S3D_SPRITE_ORDER:** This bit controls the blending order of the sprite planes for S3D support: 0 = Sprite A first. The first line or pixel comes from Sprite A (default) 1 = Sprite B first. The first line or pixel comes from Sprite B
11:10	0b RW	**S3D_SPRITE_INTERLEAVING_FORMAT:** These bits control the Sprite A/B interleaving format in S3D mode 00 = No interleaving 01 = Line interleaving 10 = Pixel interleaving 11 = Reserved

Bit Range	Default & Access	Description
9:8	0b RW	**RESERVED:** [DevCDV, DevVLVP] MBZ Scrambling enable [DevCTG]: This bit enables scrambling for DisplayPort. Software must set this bit appropriately when enabling a DisplayPort output. 00 = Scrambling disabled (Default) 01 = Scrambling enabled, no SR after initialization at loop 2 of training 10 - RESERVED 11 = Scrambling and SR enabled. Scrambling is reset every 512 BS symbols.
7:5	0b RW	**BITS_PER_COLOR:** [DevCTG, DevCDV, DevVLVP]: This field selects the number of bits per color sent to a receiver device connected to this port. Color format takes place on the Vblank after being written. Color format change can be done independent of a pixel clock change in DisplayPort. Selecting a pixel color depth higher or lower than the pixel color depth of the frame buffer results in dithering the output stream. For further details on Display Port fixed frequency programming to accommodate these formats refer to DP Frequency Programming in DPLL section of Bspec. 000 = 8 bits per color (Default) 001 = 10 bits per color 010 = 6 bits per color 011 = RESERVED 1xx = RESERVED
4	0b RW	**DITHERING_ENABLE:** [DevCTG, DevCDV]: This bit enables dithering for DisplayPort 6bpc or 8bpc modes 0 Dithering disabled (Default) 1 Dithering enabled Programming note: Dithering should only be enabled for 8 bpc or 6 bpc.
3:2	0b RW	**DITHERING_TYPE:** [DevCTG, DevCDV]: This bit selects dithering type for DisplayPort 6bpc or 8bpc modes 00 - Spatial only (default) 01- Spatio-Temporal 1 10- Spatio-Temporal 2 (testmode) 11- Temporal only (testmode)
1	0b RW	**DDA_RESET_TEST_MODE:** [DevCTG, DevCDV]: 0 Do not reset DDA 1 Reset DDA every 8th display frame
0	0b RW	**RESERVED_1:** Write as zero

Bit Range	Default & Access	Description
31:6	0b RW	**CURSOR_BASE_ADDRESS:** . This field specifies bits 31:6 of the graphics address of the base of the cursor. On [DevBW] and [DevCL] if the cursor is a popup, this field specifies bits 31:6 of the physical address of the base of the cursor, and bits 35:32 of the address are specified in the LSBs of this register. Popup cursor mode is selected within the CURACNTR register.The cursor surface address must be 4K byte aligned. The cursor must be in linear memory, it cannot be tiled. When performing 180 rotation, this offset must be the difference between the last pixel of the last line of the cursor data in its unrotated orientation and the cursor surface address. A write to this register also acts as a trigger event to force the update of active registers from the staging registers on the next display event. Each cursor register is double-buffered. The CPU writes to a set of holding registers. The active registers are updated from the holding registers following the leading edge of the vertical blank pulse. Pipe B Configuration Register

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

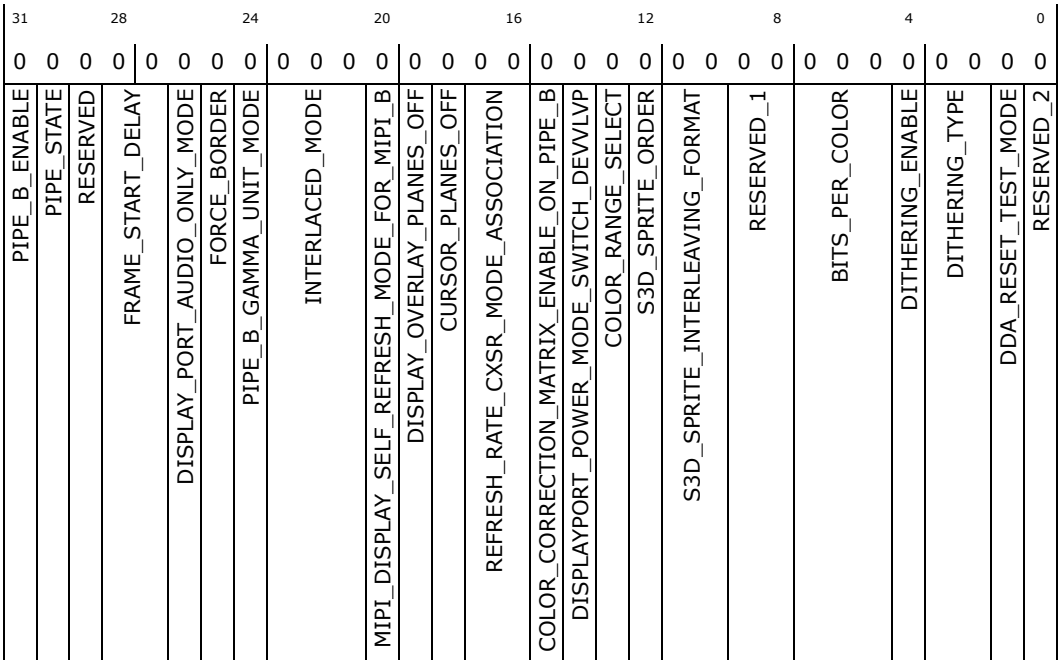
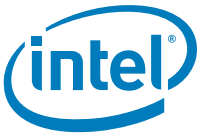
PIPEBCONF: [GTTMMADR_LSB + 2BF20h] + 71008h

GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)

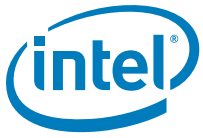
GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

Default: 00000000h





Bit Range	Default & Access	Description
31	0b RW	**PIPE_B_ENABLE:** Setting this bit to the value of one, turns on pipe B. This must be done before any planes are enabled on this pipe. Changing it to a zero should only be done when all planes that are assigned to this pipe have been disabled. Turning the pipe enable bit off disables the timing generator in this pipe. Plane disable occurs after the next VBLANK event after the plane is disabled. Synchronization pulses to the display are not maintained if the timing generator is disabled. Power consumption will be at its lowest state when disabled. A separate bit controls the DPLL enable for this pipe. Pipe timing registers should contain valid values before this bit is enabled. Disabling the Pipe and changing the timing registers and re-enabling the pipe before the next VBLANK will cause the mode change to occur at the end of the current frame. This requires no wait on the software s part. On the other hand, if this is the disabling of the pipe, that does require a software wait for VBLANK to occur. Synchronization pulses to the display are not maintained if the timing generator is disabled. Power consumption is at it s lowest state. 1 = Enable 0 = Disable
30	0b RO	**PIPE_STATE:** This bit indicates the actual state of the pipe. Since there can be some delay between disabling the pipe and the pipe actually shutting off, this bit indicates the true current state of the pipe. 0 = Disabled 1 = Enabled AccessType: Read Only
29	0b RW	**RESERVED:** Write as zero.
28:27	0b RW	**FRAME_START_DELAY:** Used to delay the frame start signal that is sent to the display planes. Normal operation uses the default 00 value and test modes can use the delayed frame start to shorten the test time. This would be set to 00 for normal operation. 00 = Frame Start occurs on the first HBLANK after the start of VBLANK 01 = Frame Start occurs on the second HBLANK after the start of VBLANK 10 = Frame Start occurs on the third HBLANK after the start of VBLANK 11 = Frame Start occurs on the forth HBLANK after the start of VBLANK
26	0b RW	**DISPLAY_PORT_AUDIO_ONLY_MODE:** [DevVLVP] Setting this bit to 1 indicates the DisplayPort will output audio only. 0 = DisplayPort will output Video or Video and Audio 1 = DisplayPort will output Audio only
25	0b RW	**FORCE_BORDER:** : (TEST MODE)0 = Normal Operation 1 = Color information is ignored and border color is substituted during active region
24	0b RW	**PIPE_B_GAMMA_UNIT_MODE:** . This bit selects which mode the pipe gamma correction logic works in. In the palette mode, it behaves as a 3X256x8 RAM lookup. VGA and indexed mode operation should use the palette in 8-bit mode. In the 10-bit gamma mode, it will act as a piecewise linear interpolation. Other gamma units such as in the overlay and sprite are unaffected by this bit.0 = 8-bit Palette Mode 1 = 10-bit Gamma Mode



Bit Range	Default & Access	Description
23:21	0b RW	**INTERLACED_MODE:** These bits are used for software control of interlaced behavior. They are updated immediately if the pipe is off, or in the vertical blank after programming if pipe is enabled. 0xx = Progressive 100 = Interlaced embedded panel using programmable vertical sync shift (2x) 101 = Interlaced using vertical sync shift. Backup option to setting 110. (2x) 110 = Interlaced with VSYNC/HSYNC Field Indication using legacy vertical sync shift. Used for SDVO. 111 = Interlaced with Field 0 Only using legacy vertical sync shift. Not used. Note: VGA display modes, sDVO line stall, and Panel fitting do not work while in interlaced modes Setting the Interlaced embedded panel mode causes hardware to automatically modify the output to match the specifications of panels that support interlaced mode.
20	0b RW	**MIPI_DISPLAY_SELF_REFRESH_MODE_FOR_MIPI_B:** .0 = Normal Operation, display controller generate timing and refresh display panel at refresh rate 1 = Display self-refresh mode. Display controller update frame buffer in display module on demand only
19	0b RW	**DISPLAY_OVERLAY_PLANES_OFF:** . This bit when set will cause all enabled Display and overlay planes that are assigned to this pipe to be disabled by overriding the current setting of the plane enable bit, at the next VBLANK. Timing signals continue as they were but the screen becomes blank. Setting the bit back to a zero will then allow the display and overlay planes to resume on the following VBLANK.0 = Normal Operation 1 = Planes assigned to this pipe are disabled.
18	0b RW	**CURSOR_PLANES_OFF:** . This bit when set will cause all enabled cursor planes that are assigned to this pipe to be disabled by overriding the current setting of the plane enable bit, at the next VBLANK. Timing signals continue as they were but the screen becomes blank. Setting the bit back to a zero will then allow the cursor planes to resume on the following VBLANK. 0 = Normal Operation 1 = Planes assigned to this pipe are disabled.
17:16	0b RW	**REFRESH_RATE_CXSR_MODE_ASSOCIATION:** These bits select how refresh rates are tied to CxSR on pipe B. When they are set to anything other than 00, bits 23:21 of this register must be programmed to 0xx. Switching between 01 and 10 settings directly is not allowed. Software must program this field to 00 before switching. Software is responsible for enabling this mode only for integrated dispay panels that support corresponding mode. 00 Default no dynamic refresh rate change enabled. Software control only. 01 Progressive-to-progressive refresh rate change enabled and tied to CxSR. Pixel clock values set in FPB0/FPB1 settings in the DPLLB control register and FPB0/FPB1 divider registers. 10 Progressive-to-interlaced refresh rate change enabled and tied to CxSR. Pixel clock value does not change in this case. Scaling must be disabled in this mode. Uses programmable VS shift 11 Reserved
15	0b RW	**COLOR_CORRECTION_MATRIX_ENABLE_ON_PIPE_B:** 1 = Color Correction Coefficients are enabled to perform color correction 0 = Color Correction Coefficients are disabled
14	0b RW	**DISPLAYPORT_POWER_MODE_SWITCH_DEVVLVP:** This bit selects the software controlled progressive to progressive power saving mode (software controlled DRRS). Hardware Controlled Refresh Rate Select must be disabled when enabling this. Link and data M/N 1 values are used for normal settings, M/N 2 values are used for low power settings. 0 Normal progressive refresh rate (default) 1 Low Power progressive refresh rate

Bit Range	Default & Access	Description
13	0b RW	**COLOR_RANGE_SELECT:** [DevVLVP]: This bit is used to select the color range of RBG outputs. 0 = Apply full 0-255 color range to the output (Default) 1 = Apply 16-235 color range to the output
12	0b RW	**S3D_SPRITE_ORDER:** This bit controls the blending order of the sprite planes for S3D support: 0 = Sprite C first. The first line or pixel comes from Sprite C (default) 1 = Sprite D first. The first line or pixel comes from Sprite D
11:10	0b RW	**S3D_SPRITE_INTERLEAVING_FORMAT:** These bits control the Sprite C/D interleaving format in S3D mode 00 = No interleaving 01 = Line interleaving 10 = Pixel interleaving 11 = Reserved
9:8	0b RW	**RESERVED_1:** [DevCDV, DevVLVP] MBZ Scrambling enable [DevCTG]: This bit enables scrambling for DisplayPort. Software must set this bit appropriately when enabling a DisplayPort output. 00 = Scrambling disabled (Default) 01 = Scrambling enabled, no SR after initialization at loop 2 of training 10 - RESERVED 11 = Scrambling and SR enabled. Scrambling is reset every 512 BS symbols.
7:5	0b RW	**BITS_PER_COLOR:** [DevCTG, DevCDV, DevVLVP]: This field selects the number of bits per color sent to a receiver device connected to this port. Color format takes place on the Vblank after being written. Color format change can be done independent of a pixel clock change. Selecting a pixel color depth higher or lower than the pixel color depth of the frame buffer results in dithering the output stream. For further details on Display Port fixed frequency programming to accommodate these formats refer to DP Frequency Programming in DPLL section of Bspec. 000 = 8 bits per color (Default) 001 = 10 bits per color 010 = 6 bits per color 011 = RESERVED 1xx = RESERVED
4	0b RW	**DITHERING_ENABLE:** [DevCTG, DevCDV]: This bit enables dithering for DisplayPort 6bpc or 8bpc modes 0 Dithering disabled (Default) 1 Dithering enabled Programming Note: Dithering should only be enabled for 8bpc or 6bpc.
3:2	0b RW	**DITHERING_TYPE:** [DevCTG, DevCDV]: This bit selects dithering type for DisplayPort 6bpc or 8bpc modes 00 - Spatial only (default) 01- Spatio-Temporal 1 10- Spatio-Temporal 2 (testmode) 11- Temporal only (testmode)
1	0b RW	**DDA_RESET_TEST_MODE:** [DevCTG, DevCDV]: 0 Do not reset DDA 1 Reset DDA every 8th display frame

Bit Range	Default & Access	Description
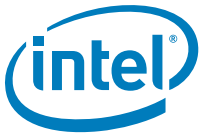
31	0b RW	**VGA_DISPLAY_DISABLE:** This bit will disable the VGA compatible display mode. It has no effect on VGA register or A0000-BFFFF memory aperture accesses which are controlled by the PCI configuration and VGA register settings. VGA display should only be enabled if all display planes other than VGA are disabled. After enabling the VGA, most display planes need to stay disabled, only the VGA popup (cursor A) can be enabled. The VGA display is never trusted. No secrets are allowed in the pre-allocated memory and VGA is limited to access only that memory. During trusted operation (when registers are locked via Lock), this bit will always act as if it was set to a one (disabled VGA display). VGA 132 Column text mode is not supported. 0 = VGA Display Enabled 1 = VGA Display Disabled
30	0b RW	**VGA_POP_UP_2X_CENTERED_MODE_SCALING:** When this bit is set to a one, the VGA and pop-up data is scaled using pixel doubling in both the horizontal and vertical direction for use on un-scaled flat panel displays. Setting this bit allows the VGA to run at higher dot clock frequencies and creates a larger (4x the size) image for better quality on larger displays. It is intended for use in one of the centering modes when not using the internal panel fitting. Do not use it for native VGA modes or when internal panel fitting is used to scale VGA. In the situations where it is used, for 1280 wide or larger panels this bit should be set. For exactly 1280 wide panels, the Nine-dot disable bit should also be set. This operation is in addition to the VGA functions that double the pixels and lines. 0 = VGA display is normal size 1 = VGA and VGA popup data is doubled in the horizontal and vertical direction.

Bit Range	Default & Access	Description
29	0b RW	**VGA_PIPE_SELECT:** This bit only applies to devices with dual pipe support. For devices with a single display pipe, this bit will be ignored. For dual pipe devices, this bit determines which pipe is to receive the VGA display data. This must be changed only when the VGA display is in the disabled state via the VGA display disable bit or during the write to enable VGA display. 0 = Selects Assigns the VGA display to Pipe A 1 = Selects Assigns the VGA display to Pipe B
28:27	0b RW	**RESERVED_:** Software must preserve the contents of these bits.
26	0b RW	**VGA_BORDER_ENABLE:** This bit determines if the VGA border areas during VGA centering modes are included in the active display area and do or do not appear on integrated TV encoder output and devices that use centering such as on DVO connected flat panel, TV displays, or integrated panels. For use with the internal panel fitting logic, the border if enabled will be scaled along with the pixel data. Setting this bit allows the popup to be positioned overlapping the border area of the image. 0 = VGA Border areas are not included in the image size calculations for centering only active area. 1 = VGA Border areas are enabled and is passed to the display pipe for display and used in the image size calculation for centering modes
25:24	0b RW	**VGA_CENTERING_ENABLE:** VGA centering modes use the pipe timing generators to determine the actual display timings. This would normally correspond to the display panel size and timings. The VGA registers determine the centered VGA image height and width. The VGA border may or may not be considered in the calculation selected by the VGA Border Enable bit. For a proper image, the VGA image size should not exceed the pipe timing generator active rectangle. When using the internal panel fitting logic, the horizontal image size needs to be less than or equal to 2048 pixels to generate a proper image. The VGA image will either be centered within the pipe timing rectangle or appear in the upper left corner. Upper left corner centered mode is generally used for external panel scaling where the DVO stall signal is used and is always used for internal panel fitting operation. When panel fitter is enabled on the same pipe as VGA this register setting is ignored and upper left corner centered mode is always selected. When centering is disabled, the VGA CRTC registers determine the display timing compatible with legacy VGA devices for driving CRT like devices. 00 = VGA centering is disabled, VGA operates in Native VGA mode or when driving integrated TV 01 = VGA centering is enabled, VGA image appears in the center of the larger rectangle 10 = VGA centering is enabled, VGA image appears in the upper left corner of the larger rectangle 11 = VGA centering is enabled, VGA image appears in the upper left corner of the larger rectangle
23	0b RW	**VGA_PALETTE_READ_SELECT:** This bit only applies to dual display pipe devices and determines which palette VGA palette read accesses will occur from. 0 = VGA palette reads will access Palette A (default). 1 = VGA palette reads will access Palette B VGA palette reads are reads from I/O address 0x3c9.
22	0b RW	**VGA_PALETTE_A_WRITE_DISABLE:** This determines which palette the VGA palette writes will have as a destination. One or both palettes can be the destination. If both are disabled, writes will not affect the palette RAM contents. 0 = VGA palette writes will update Palette A (default). 1 = VGA palette writes will not update Palette A VGA palette writes are writes to I/O address 0x3C9h.



Bit Range	Default & Access	Description
21	0b RW	**DUAL_PIPE_VGA_PALETTE_B_WRITE_DISABLE:** This determines which palette the VGA palette writes will have as a destination. One or both palettes can be the destination. If both are disabled, writes will not affect the palette RAM contents. 0 = VGA palette writes will update Palette B (default). 1 = VGA palette writes will not update Palette B VGA palette writes are writes to I/O address 0x3C9h.
20	0b RW	**LEGACY_VGA_8_BIT_PALETTE_ENABLE:** This bit only affects reads and writes to the palette through VGA I/O addresses. In the 6-bit mode, the 8-bits of data are shifted up two bits on the write (upper two bits are lost) and shifted two bits down on the read. It provides backward compatibility for original VGA programs (in it s default state) as well as VESA VBE support for 8-bit palette. It does not affect palette accesses through the palette register MMIO path. 0 = 6-bit DAC (default). 1 = 8-bit DAC.
19	0b RW	**PALETTE_BYPASS_TEST_MODE:** 0 = Pass VGA data through the palette for translation (Normal Operation) 1 = Bypass the palette for allowing testing without loading palette both VGA and popup data will bypass the palette in this mode.
18	0b RW	**NINE_DOT_DISABLE:** Prevents DOS applications from setting the VGA display into a real 9-dot per character operation mode, instead the device emulates that using 8-dots per character. This is intended to provide VGA compatibility on DVI type connectors and integrated panels where there would otherwise not be room for the 720 horizontal pixels or 1440 pixels when horizontally doubled. The VGA register bit SR01(0) functionality is disabled. VGA panning control handles the pseudo 9-dot mode when both this bit is set and SR01(0) is clear. 0 = Enable use of 9-dot enable bit in VGA registers 1 = Ignore the 9-dot per character bit and always use 8
17	0b RW	**RESERVED:** Reserved.
16:8	0b RW	**RESERVED__1:** Software must preserve the contents of these bits.

5:0	0b RW	**VSYNC_BLINK_RATE:** Controls the VGA blink rate in terms of the number of VSYNCs per on/off cycle. These bits are programmed with the (VSYNCs/cycle)/2-1. The proper programming of this register is determined by the VSYNC rate that the display requires when in a VGA display mode.

GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)

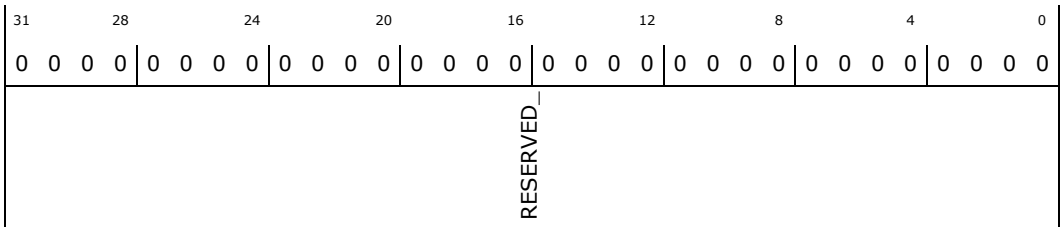
Default: 00000000h



Bit Range	Default & Access	Description
31	0b RW	**SPRITE_A_ENABLE:** This bit will enable or disable the Sprite A. When this bit is set, the plane will generate pixels for display to be combined by the blender for the target pipe. When set to zero, memory fetches cease and display is blanked (from this plane) at the next VBLANK event from the pipe that this plane is assigned. At least one of the display pipes must be enabled to enable this plane. There is an override for the enable of this plane in the Pipe Configuration register. This bit only has an effect when the plane is not trusted. When the plane is marked trusted, this bit will be overridden and the display disabled when the registers are unlocked. 1 = Enable 0 = Disable
30	0b RW	**SPRITE_A_GAMMA_ENABLE:** There are two gamma adjustments possible in the Sprite A data path. This bit controls the gamma correction in the display pipe not the gamma control in this plane. It affects only the pixel data from this display plane. For pixel format of 8-bit indexed, this bit should be set to a one. Gamma correction logic that is contained in the Sprite A logic is disabled by loading the default values into those registers. When this plane is marked as trusted, this bit should always be set to zero to force the pipe gamma to be always be bypassed. 0 = Sprite A pixel data bypasses the display pipe gamma correction logic (default). 1 = Sprite A pixel data is gamma corrected in the pipe gamma correction logic
29:26	0b RW	**SPRITE_A_SOURCE_PIXEL_FORMAT:** This field selects the pixel format for the sprite/Sprite A. Pixel formats with an alpha channel should not use source keying. Before entering the blender, each source format is converted to 10 bits per pixel (details are described in the intermediate precision for the blender section of the Display Functions chapter). 0000 = YUV 4:2:2 packed (see byte order below). 0001 = Reserved 0010 = 8-bpp Indexed. 0011 = Reserved. 0100 = Reserved. 0101 = 16-bit BGRX (5:6:5:0) pixel format (XGA compatible). 0110 = 32-bit BGRX (8:8:8:8) pixel format. Ignore alpha. 0111 = 32-bit BGRA (8:8:8:8) pixel format with pre-multiplied alpha channel. 1000 = 32-bit RGBX (10:10:10:2) pixel format. Ignore alpha. 1001 = 32-bit RGBA (10:10:10:2) pixel format 1010 = Reserved. 1011 = Reserved. 1100 = Reserved. 1101 = Reserved. 1110 = 32-bit RGBX (8:8:8:8) pixel format. Bit Range	Default & Access	Description
25:24	0b RW	**SPRITE_A_PIPE_SELECT:** Sprite A always ties to pipe A. Reserved.
23	0b RW	**RESERVED:** Reserved.
22	0b RW	**SPRITE_SOURCE_KEY_ENABLE:** When used as a sprite in the 16/32-bpp modes without alpha this enables source color keying. Sprite pixel values that match (within range) the key will become transparent. Setting this bit is not allowed when the Sprite A pixel format includes an alpha channel. [DevBW] Erratum: This bit must always be set to 0 when Sprite A pixel format is YUV 0 = Sprite source key is disabled (default) 1 = Sprite source key is enabled. Each sprite has built in source keying enabled/disabled. If the source keying is disabled and no alpha blending is enabled, the pixels are tagged as opaque. If sprite source keying is enabled and no alpha blending is enabled, it works as follows: For YUV sprite data, each yuv channel data is compared with the corresponding channel s key color Low and High (each channel in range can be masked out). If all three channels are in range between the low and high key values, it is considered source compared. For RGB sprite data, each 24-bit RGB pixel data is compared with the 24-bit key value (note it only uses the 24-bit Low key value for comparison). Each 24-bit has to be equal (each bit comparison can also be masked out) for the source compared. If the sprite source data compare and matches, then the sprite data will be tagged as transparent when blending with its destination pixel. If the sprite source data does not compare, then the sprite data will be tagged as opaque when blending with its destination pixel.
21:20	0b RW	**PIXEL_MULTIPLY:** This cause the display plane to duplicate lines and pixels sent to the assigned pipe. In the line/pixel doubling mode, the horizontal pixels are doubled and lines are sent twice. This is a method of scaling the source image by two (both H and V). 00 = No line/Pixel duplication 01 = Line/Pixel Doubling 10 = Line Doubling only 11 = Pixel Doubling only
19	0b RW	**COLOR_CONVERSION_DISABLED:** This bit enables or disables the color conversion logic. Color conversion is intended to be used with the formats that support YUV formats such as the YUV 4:2:2 packed format and x:8:8:8 and 8:8:8:8 formats. Formats such as RGB5:5:5 and 5:6:5 do not have YUV versions. 0 = Pixel data is sent through the conversion logic (only applies to YUV formats) 1 = Pixel data is not sent through the YUV-)RGB conversion logic.
18	0b RW	**YUV_FORMAT:** This bit specifies the source YUV format for the YUV to RGB color conversion operation. This field is ignored when source data is RGB. 0 = ITU-R Recommendation BT.601 1 = ITU-R Recommendation BT.709
17:16	0b RW	**YUV_BYTE_ORDER:** This field is used to select the byte order when using YUV 4:2:2 data formats. For other formats, this field is ignored. 00 = YUYV 01 = UYVY 10 = YVYU 11 = VYUY
15	0b RW	**_180DISPLAY_ROTATION:** This mode causes the display plane to be rotated 180 . In addition to setting this bit, software must also set the base address to the lower right corner of the unrotated image and calculate the x, y offset as relative to the lower right corner. 0 = No rotation 1 = 180 rotation

Only X tiling is supported for display surfaces. When this bit is set, it affects the hardware interpretation of the DSPCTILEOFF, DSPCLINOFF, and DSPCSURFADDR registers. 0 = Sprite A surface uses linear memory 1 = Sprite A surface uses X-tiled memory
9:3	0b RW	**RESERVED_2:** Write as zero
2	0b RW	**SPRITE_A_BOTTOM:** This bit will force the Sprite A plane to be on the bottom of the Z order. Default: 00000000h

Bit Range	Default & Access	Description
31:0	0b RW	**SPRITE_A_OFFSET:** This register provides the panning offset into the Sprite A plane. This value is added to the surface address to get the graphics address of the first pixel to be displayed. This offset must be at least pixel aligned. This offset is the difference between the address of the upper left pixel to be displayed and the display surface address. When performing 180 rotation, this offset must be the difference between the last pixel of the last line of the display data in its unrotated orientation and the display surface address.

Access Method

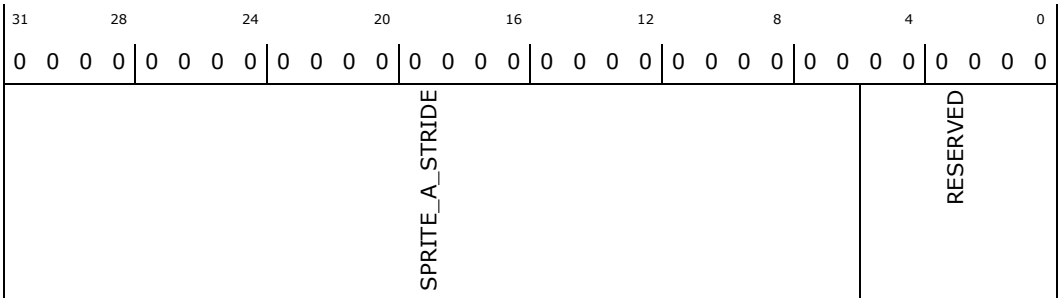
GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)
GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:6	0b RW	**SPRITE_A_STRIDE:** This is the stride for Sprite A in bytes. When using linear memory, this must be 64 byte aligned. When using tiled memory, this must be 256 byte aligned. This register is updated through a command packet passed through the command stream or writes to this register. When it is desired to update both this and the start register, the stride register must be written first because the write to the start register is the trigger that causes the update of both registers on the next VBLANK event. When using tiled memory, the actual memory buffer stride is limited to a maximum of 16K bytes.

This field can be used in two modes. When full range YUV data is operated on, this field contains the saturation value. When the range-limited YCbCr data is used, software should program this field with the product of the saturation multiplier value multiplied by the CbCr range scale factor (=128/112). Similar to the contrast field, there is no limit for saturation reduction saturation = 0 means all pixels become the same value. However, increasing contrast can only be increased by a factor less than 8. For example, the largest contrast with value of 0x7.7F can bring input range [0, 32] to a full display color range of [0, 255]. Bypassing Hue, even for source data in RGB format, is accomplished by programming this field to 0.0.

GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)

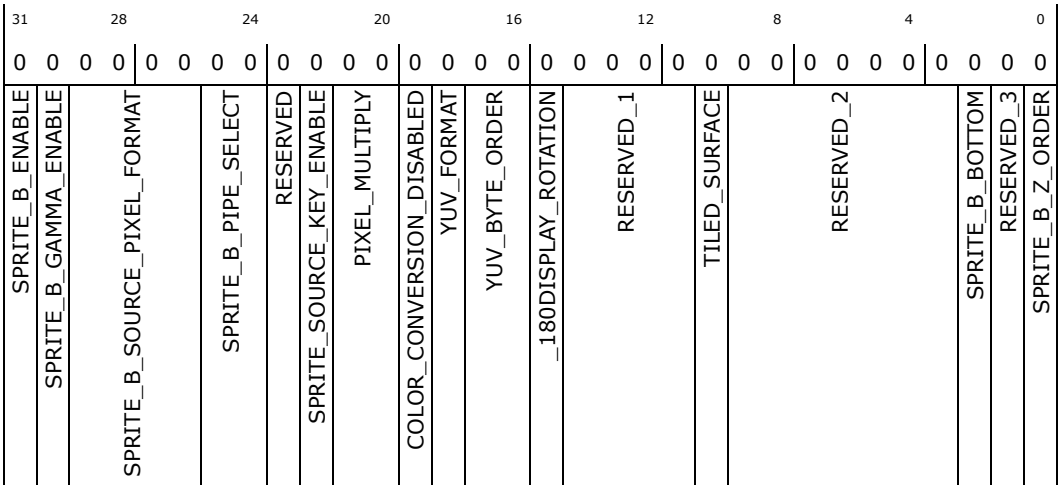
Default: 00000000h



Bit Range	Default & Access	Description
31	0b RW	**SPRITE_B_ENABLE:** This bit will enable or disable the Sprite B. When this bit is set, the plane will generate pixels for display to be combined by the blender for the target pipe. When set to zero, memory fetches cease and display is blanked (from this plane) at the next VBLANK event from the pipe that this plane is assigned. At least one of the display pipes must be enabled to enable this plane. There is an override for the enable of this plane in the Pipe Configuration register. This bit only has an effect when the plane is not trusted. When the plane is marked trusted, this bit will be overridden and the display disabled when the registers are unlocked. 1 = Enable 0 = Disable
30	0b RW	**SPRITE_B_GAMMA_ENABLE:** There are two gamma adjustments possible in the Sprite B data path. This bit controls the gamma correction in the display pipe not the gamma control in this plane. It affects only the pixel data from this display plane. For pixel format of 8-bit indexed, this bit should be set to a one. Gamma correction logic that is contained in the Sprite B logic is disabled by loading the default values into those registers. When this plane is marked as trusted, this bit should always be set to zero to force the pipe gamma to be always be bypassed. 0 = Sprite B pixel data bypasses the display pipe gamma correction logic (default). 1 = Sprite B pixel data is gamma corrected in the pipe gamma correction logic
29:26	0b RW	**SPRITE_B_SOURCE_PIXEL_FORMAT:** This field selects the pixel format for the sprite/Sprite B. Pixel formats with an alpha channel should not use source keying. Before entering the blender, each source format is converted to 10 bits per pixel (details are described in the intermediate precision for the blender section of the Display Functions chapter). 0000 = YUV 4:2:2 packed (see byte order below). 0001 = Reserved 0010 = 8-bpp Indexed. 0011 = Reserved. 0100 = Reserved. 0101 = 16-bit BGRX (5:6:5:0) pixel format (XGA compatible). 0110 = 32-bit BGRX (8:8:8:8) pixel format. Ignore alpha. 0111 = 32-bit BGRA (8:8:8:8) pixel format with pre-multiplied alpha channel. 1000 = 32-bit RGBX (10:10:10:2) pixel format. Ignore alpha. 1001 = 32-bit RGBA (10:10:10:2) pixel format 1010 = Reserved. 1011 = Reserved. 1100 = Reserved. 1101 = Reserved. 1110 = 32-bit RGBX (8:8:8:8) pixel format. Ignore alpha. 1111 = 32-bit RGBA (8:8:8:8)

Bit Range	Default & Access	Description
23	0b RW	**RESERVED:** Reserved.
22	0b RW	**SPRITE_SOURCE_KEY_ENABLE:** When used as a sprite in the 16/32-bpp modes without alpha this enables source color keying. Sprite pixel values that match (within range) the key will become transparent. Setting this bit is not allowed when the Sprite B pixel format includes an alpha channel. [DevBW] Erratum: This bit must always be set to 0 when Sprite B pixel format is YUV 0 = Sprite source key is disabled (default) 1 = Sprite source key is enabled.
21:20	0b RW	**PIXEL_MULTIPLY:** This cause the display plane to duplicate lines and pixels sent to the assigned pipe. In the line/pixel doubling mode, the horizontal pixels are doubled and lines are sent twice. This is a method of scaling the source image by two (both H and V). 00 = No line/Pixel duplication 01 = Line/Pixel Doubling 10 = Line Doubling only 11 = Pixel Doubling only
19	0b RW	**COLOR_CONVERSION_DISABLED:** This bit enables or disables the color conversion logic. Color conversion is intended to be used with the formats that support YUV formats such as the YUV 4:2:2 packed format and x:8:8:8 and 8:8:8:8 formats. Formats such as RGB5:5:5 and 5:6:5 do not have YUV versions. 0 = Pixel data is sent through the conversion logic (only applies to YUV formats) 1 = Pixel data is not sent through the YUV-)RGB conversion logic.
18	0b RW	**YUV_FORMAT:** This bit specifies the source YUV format for the YUV to RGB color conversion operation. This field is ignored when source data is RGB. 0 = ITU-R Recommendation BT.601 1 = ITU-R Recommendation BT.709
17:16	0b RW	**YUV_BYTE_ORDER:** This field is used to select the byte order when using YUV 4:2:2 data formats. For other formats, this field is ignored. 00 = YUYV 01 = UYVY 10 = YVYU 11 = VYUY
15	0b RW	**_180DISPLAY_ROTATION:** This mode causes the display plane to be rotated 180 . In addition to setting this bit, software must also set the base address to the lower right corner of the unrotated image and calculate the x, y offset as relative to the lower right corner. 0 = No rotation 1 = 180 rotation
14:11	0b RW	**RESERVED_1:** Reserved.
10	0b RW	**TILED_SURFACE:** This bit indicates that the Sprite B surface data is in tiled memory. The tile pitch is specified in bytes in the DSPCSTRIDE register. Only X tiling is supported for display surfaces. When this bit is set, it affects the hardware interpretation of the DSPCTILEOFF, DSPCLINOFF, and DSPCSURFADDR registers. 0 = Sprite B surface uses linear memory 1 = Sprite B surface uses X-tiled memory
9:3	0b RW	**RESERVED_2:** Write as zero
2	0b RW	**SPRITE_B_BOTTOM:** This bit will force the Sprite B plane to be on the bottom of the Z order. If the plane is marked as trusted, it only applies to the Z order of the trusted planes. 0 = Sprite B Z order is determined by the other control bits 1 = Sprite B is forced to be on the bottom of the Z order.

26:18	001000000b RW	**CONTRAST:** Contrast adjustment applies to YUV data. The Y channel is multiplied by the value contained in the register field. This signed fixed-point number is in 3i.6f format with the first 3 MSBs as the integer value and the last 6 LSBs as the fraction value. The allowed contrast value ranges from 0 to 7.53125 decimal. Bypassing Contrast, for YUV modes and for source data in RGB format, is accomplished by programming this field to a field value that represents 1.0 decimal or 001.000000 binary .

7:0	0b RW	**BRIGHTNESS:** This field provides the brightness adjustment with a 8-bit 2 s compliment value ranging [-128, +127]. This value is added to the Y value after contrast multiply and before YUV to RGB conversion. A value of zero disables this adjustment affect. This 8-bit signed value provides half of the achievable brightness adjustment dynamic range. A full range brightness value would have a programmable range of [-255, +255]. Bypassing Brightness for YUV formats and for source data in RGB format, is accomplished by programming this field to 0.

When the range-limited YCbCr data is used, software should program this field with the product of the saturation multiplier value multiplied by the CbCr range scale factor (=128/112). Similar to the contrast field, there is no limit for saturation reduction saturation = 0 means all pixels become the same value. However, increasing contrast can only be increased by a factor less than 8. For example, the largest contrast with value of 0x7.7F can bring input range [0, 32] to a full display color range of [0, 255]. Bypassing Hue, even for source data in RGB format, is accomplished by programming this field to 0.0.

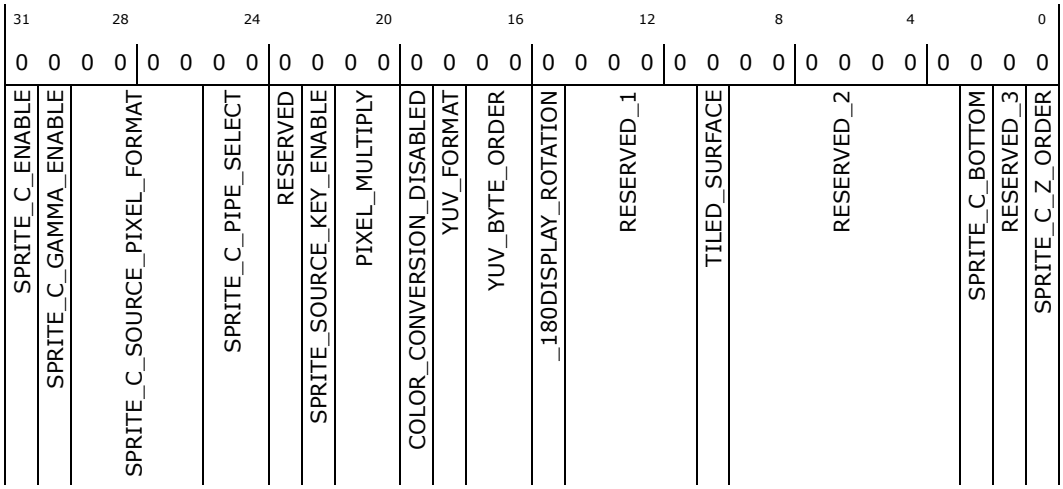
Default: 00000000h



Bit Range	Default & Access	Description
31	0b RW	**SPRITE_C_ENABLE:** This bit will enable or disable the Sprite C. When this bit is set, the plane will generate pixels for display to be combined by the blender for the target pipe. When set to zero, memory fetches cease and display is blanked (from this plane) at the next VBLANK event from the pipe that this plane is assigned. At least one of the display pipes must be enabled to enable this plane. There is an override for the enable of this plane in the Pipe Configuration register. This bit only has an effect when the plane is not trusted. When the plane is marked trusted, this bit will be overridden and the display disabled when the registers are unlocked. 1 = Enable 0 = Disable
30	0b RW	**SPRITE_C_GAMMA_ENABLE:** There are two gamma adjustments possible in the Sprite C data path. This bit controls the gamma correction in the display pipe not the gamma control in this plane. It affects only the pixel data from this display plane. For pixel format of 8-bit indexed, this bit should be set to a one. Gamma correction logic that is contained in the Sprite C logic is disabled by loading the default values into those registers. When this plane is marked as trusted, this bit should always be set to zero to force the pipe gamma to be always be bypassed. 0 = Sprite C pixel data bypasses the display pipe gamma correction logic (default). 1 = Sprite C pixel data is gamma corrected in the pipe gamma correction logic
29:26	0b RW	**SPRITE_C_SOURCE_PIXEL_FORMAT:** This field selects the pixel format for the sprite/Sprite C. Pixel formats with an alpha channel should not use source keying. Before entering the blender, each source format is converted to 10 bits per pixel (details are described in the intermediate precision for the blender section of the Display Functions chapter). 0000 = YUV 4:2:2 packed (see byte order below). 0001 = Reserved 0010 = 8-bpp Indexed. 0011 = Reserved. 0100 = Reserved. 0101 = 16-bit BGRX (5:6:5:0) pixel format (XGA compatible). 0110 = 32-bit BGRX (8:8:8:8) pixel format. Bit Range	Default & Access	Description
23	0b RW	**RESERVED:** Reserved.
22	0b RW	**SPRITE_SOURCE_KEY_ENABLE:** When used as a sprite in the 16/32-bpp modes without alpha this enables source color keying. Sprite pixel values that match (within range) the key will become transparent. Setting this bit is not allowed when the Sprite C pixel format includes an alpha channel. [DevBW] Erratum: This bit must always be set to 0 when Sprite C pixel format is YUV 0 = Sprite source key is disabled (default) 1 = Sprite source key is enabled.
21:20	0b RW	**PIXEL_MULTIPLY:** This cause the display plane to duplicate lines and pixels sent to the assigned pipe. In the line/pixel doubling mode, the horizontal pixels are doubled and lines are sent twice. This is a method of scaling the source image by two (both H and V). 00 = No line/Pixel duplication 01 = Line/Pixel Doubling 10 = Line Doubling only 11 = Pixel Doubling only
19	0b RW	**COLOR_CONVERSION_DISABLED:** This bit enables or disables the color conversion logic. Color conversion is intended to be used with the formats that support YUV formats such as the YUV 4:2:2 packed format and x:8:8:8 and 8:8:8:8 formats. Formats such as RGB5:5:5 and 5:6:5 do not have YUV versions. 0 = Pixel data is sent through the conversion logic (only applies to YUV formats) 1 = Pixel data is not sent through the YUV-)RGB conversion logic.
18	0b RW	**YUV_FORMAT:** This bit specifies the source YUV format for the YUV to RGB color conversion operation. This field is ignored when source data is RGB. 0 = ITU-R Recommendation BT.601 1 = ITU-R Recommendation BT.709
17:16	0b RW	**YUV_BYTE_ORDER:** This field is used to select the byte order when using YUV 4:2:2 data formats. For other formats, this field is ignored. 00 = YUYV 01 = UYVY 10 = YVYU 11 = VYUY
15	0b RW	**_180DISPLAY_ROTATION:** This mode causes the display plane to be rotated 180 . In addition to setting this bit, software must also set the base address to the lower right corner of the unrotated image and calculate the x, y offset as relative to the lower right corner. 0 = No rotation 1 = 180 rotation
14:11	0b RW	**RESERVED_1:** Reserved.
10	0b RW	**TILED_SURFACE:** This bit indicates that the Sprite C surface data is in tiled memory. The tile pitch is specified in bytes in the DSPCSTRIDE register. Only X tiling is supported for display surfaces. When this bit is set, it affects the hardware interpretation of the DSPCTILEOFF, DSPCLINOFF, and DSPCSURFADDR registers. 0 = Sprite C surface uses linear memory 1 = Sprite C surface uses X-tiled memory
9:3	0b RW	**RESERVED_2:** Write as zero
2	0b RW	**SPRITE_C_BOTTOM:** This bit will force the Sprite C plane to be on the bottom of the Z order. This signed fixed-point number is in 3i.6f format with the first 3 MSBs as the integer value and the last 6 LSBs as the fraction value. The allowed contrast value ranges from 0 to 7.53125 decimal. Bypassing Contrast, for YUV modes and for source data in RGB format, is accomplished by programming this field to a field value that represents 1.0 decimal or 001.000000 binary .

Bit Range	Default & Access	Description
31	0b RW	**SPRITE_D_ENABLE:** This bit will enable or disable the Sprite D. When this bit is set, the plane will generate pixels for display to be combined by the blender for the target pipe. When set to zero, memory fetches cease and display is blanked (from this plane) at the next VBLANK event from the pipe that this plane is assigned. At least one of the display pipes must be enabled to enable this plane. There is an override for the enable of this plane in the Pipe Configuration register. This bit only has an effect when the plane is not trusted. When the plane is marked trusted, this bit will be overridden and the display disabled when the registers are unlocked. 1 = Enable 0 = Disable
30	0b RW	**SPRITE_D_GAMMA_ENABLE:** There are two gamma adjustments possible in the Sprite D data path. This bit controls the gamma correction in the display pipe not the gamma control in this plane. It affects only the pixel data from this display plane. For pixel format of 8-bit indexed, this bit should be set to a one. Gamma correction logic that is contained in the Sprite D logic is disabled by loading the default values into those registers. When this plane is marked as trusted, this bit should always be set to zero to force the pipe gamma to be always be bypassed. 0 = Sprite D pixel data bypasses the display pipe gamma correction logic (default). 1 = Sprite D pixel data is gamma corrected in the pipe gamma correction logic

When the surface is in linear memory, panning is specified using a linear offset in the DSPCLINOFF register. This address must be 4K aligned. This register can be written directly through software or by command packets in the command stream. It represents an offset from the graphics memory aperture base and is mapped to physical pages through the global GTT. If the device supports trusted operation and this plane is not marked trusted, the memory pages must not be marked NoDMA . The value in this register is updated through the command streamer during synchronous flips. [DevBW] and [DevCL]: This address must be 128K aligned for linear memory.

26:18	001000000b RW	**CONTRAST:** Contrast adjustment applies to YUV data. The Y channel is multiplied by the value contained in the register field. This signed fixed-point number is in 3i.6f format with the first 3 MSBs as the integer value and the last 6 LSBs as the fraction value. The allowed contrast value ranges from 0 to 7.53125 decimal. Bypassing Contrast, for YUV modes and for source data in RGB format, is accomplished by programming this field to a field value that represents 1.0 decimal or 001.000000 binary .
17:8	0b RW	**RESERVED_1:** Reserved.
7:0	0b RW	**BRIGHTNESS:** This field provides the brightness adjustment with a 8-bit 2 s compliment value ranging [-128, +127]. This value is added to the Y value after contrast multiply and before YUV to RGB conversion. A value of zero disables this adjustment affect. This 8-bit signed value provides half of the achievable brightness adjustment dynamic range. A full range brightness value would have a programmable range of [-255, +255]. Bypassing Brightness for YUV formats and for source data in RGB format, is accomplished by programming this field to 0.

This field can be used in two modes. When full range YUV data is operated on, this field contains the saturation value. When the range-limited YCbCr data is used, software should program this field with the product of the saturation multiplier value multiplied by the CbCr range scale factor (=128/112). Similar to the contrast field, there is no limit for saturation reduction saturation = 0 means all pixels become the same value. However, increasing contrast can only be increased by a factor less than 8. For example, the largest contrast with value of 0x7.7F can bring input range [0, 32] to a full display color range of [0, 255]. Bypassing Hue, even for source data in RGB format, is accomplished by programming this field to 0.0.

3.5.2 MSR (MSR_Write)—Offset 3C2h

Miscellaneous Output

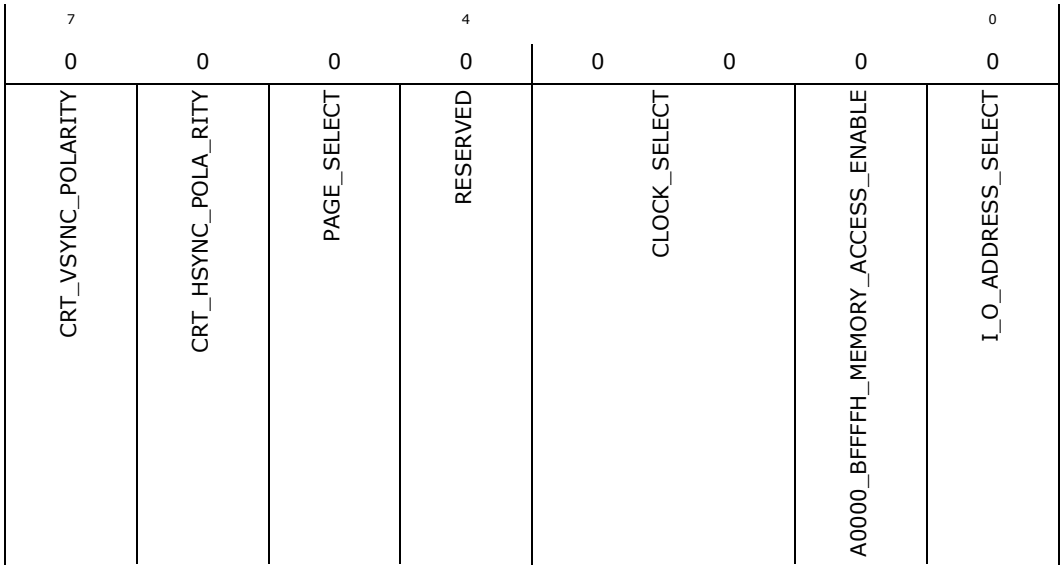
Access Method

Type: Memory Mapped I/O Register (Size: 8 bits)

MSR_Write: [GTTMMADR_LSB + 2BF20h] + 3C2h

GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)
GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

Default: 00h



Bit Range	Default & Access	Description
7	0b RW	**CRT_VSYNC_POLARITY:** This is a legacy function that is used in native VGA modes. For most cases, sync polarity will be controlled by the port control bits. The VGA settings can be optionally selected for compatibility with the original VGA when used in the VGA native mode. Sync polarity was used in VGA to signal the monitor how many lines of active display are being generated. 0 = Positive Polarity (default). 1 = Negative Polarity.
6	0b RW	**CRT_HSYNC_POLA_RITY:** This is a legacy function that is used in native VGA modes. For most cases, sync polarity will be controlled by the port control bits. The VGA settings can be optionally selected for compatibility with the original VGA when used in the VGA native mode. 0 = Positive Polarity (default). 1 = Negative Polarity
5	0b RW	**PAGE_SELECT:** In Odd/Even Memory Map Mode 1 (GR6), this bit selects the upper or lower 64 KB page in dis play memory for CPU access: 0 = Upper page (default) 1 = Lower page. Selects between two 64KB pages of frame buffer memory during standard VGA odd/even modes (modes 0h through 5h). Bit 1 of register GR06 can also program this bit in other modes. Note that this bit is would normally set to 1 by the software.
4	0b RW	**RESERVED:** Read as 0.

Bit Range	Default & Access	Description
3:2	0b RW	**CLOCK_SELECT:** These bits can select the dot clock source for the CRT interface. The bits should be used to select the dot clock in standard native VGA modes only. When in the centering or upper left corner modes, these bits should be set to have no effect on the clock rate. The actual frequencies that these bits select, if they have any affect at all, is programmable through the DPLL registers that default to the standard values used for VGA. 00 = CLK0, 25.175 MHz (for standard VGA modes with 640 pixel (8-dot) horizontal resolution) (default) 01 = CLK1, 28.322 MHz. (for standard VGA modes with 720 pixel (9-dot) horizontal resolution) 10 = Was used to select an external clock (now unused) 11 = Reserved
1	0b RW	**A0000_BFFFFH_MEMORY_ACCESS_ENABLE:** VGA Compatibility bit enables access to local video memory (frame buffer) at A0000(BFFFFh. When disabled, accesses to VGA memory are blocked in this region. This bit is independent of and does not block CPU access to the video linear frame buffer at other addresses. Note that it is typical for AGP chipsets to shadow this register to allow proper steering of memory accesses to the proper bus. 0 = Prevent CPU access to memory/registers/ROM through the A0000-BFFFF VGA memory aperture (default). 1 = Allow CPU access to memory/registers/ROM through the A0000-BFFFF VGA memory aperture. This memory must be mapped as UC by the CPU; see VGA Host Access Memory Munging in Display and Overlay Functions.
0	0b RW	**I_O_ADDRESS_SELECT:** This bit selects 3Bxh or 3Dxh as the I/O address for the CRT Controller registers, the Feature Control Register (FCR), and Input Status Register 1 (ST01). Presently ignored (whole range is claimed), but will ignore 3Bx for color configuration or 3Dx for monochrome. Note that it is typical in AGP chipsets to shadow this bit and properly steer I/O cycles to the proper bus for operation where a MDA exists on another bus such as ISA. 0 = Select 3Bxh I/O address (MDA emulation) (default). 1 = Select 3Dxh I/O address (CGA emulation).

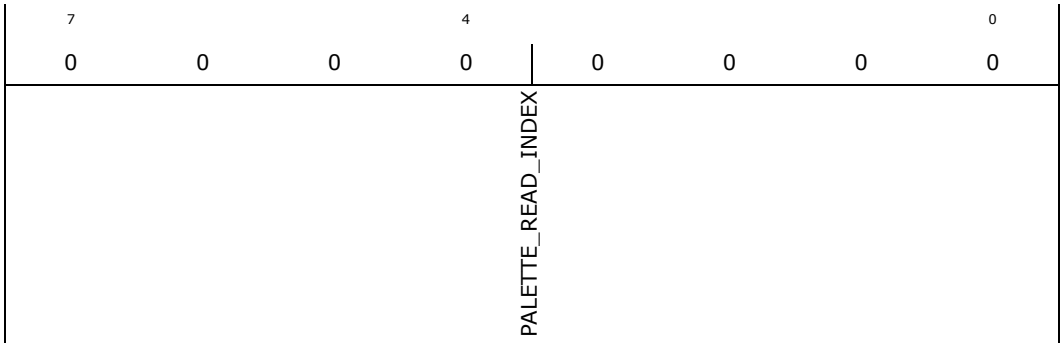
GTTMMADR_LSB Type: PCI Configuration Register (Size: 32 bits)
GTTMMADR_LSB Reference: [B:0, D:2, F:0] + 10h

Default: 00h



Bit Range	Default & Access	Description
7:0	0b WO	**PALETTE_READ_INDEX:** The 8-bit index value programmed into this register chooses which of 256 standard color data positions within the palette are to be made accessible for being read from via the Palette Data Register (DACDATA). The index value held in this register is automatically incremented when all three bytes of the color data position selected by the current index have been read. A write to this register will abort a uncompleted palette write sequence. This register allows access to the palette even when running non-VGA display modes.

With each request, the deadline sent to Pondicherry is either DN, or the sum of the global timer and MDD, whichever is larger. After each request is sent, DN is computed by adding DI for each 32Byte request sent to DN. Each cycle, DN is checked to make sure that it is either greater than the current global timer, or is less than the global timer by no more than 64 usec, else it is set to the global timer minus 64 usec.

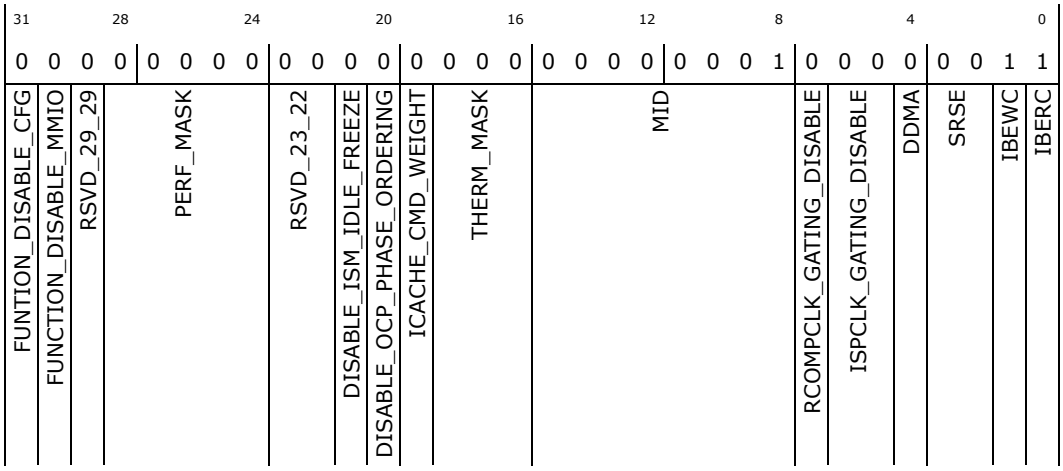
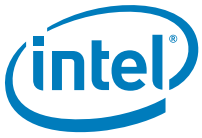
Default: 00000103h



Bit Range	Default & Access	Description
31	0b RW	**FUNTION_DISABLE_CFG:** FUNCTION_DISABLE_CFG: When set, the IUNIT stops accepting any new Configuration cycle requests on the IOSF Primary bus including any new configuration cycle requests to clear this bit. Both legacy and MSI interrupts are disabled as well.



Bit Range	Default & Access	Description
30	0b RW	**FUNCTION_DISABLE_MMIO:** FUNCTION_DISABLE_MMIO: When set, the IUNIT stops accepting any new MMIO access requests on the IOSF Primary bus.
29	0b RW	**RSVD_29_29:** Reserved
28:24	0h RW	**PERF_MASK:** PERF_MASK: This field determines the amount of performance throttling applied to ispclk. The value of this field determines how many beat periods of ispclk are killed, where a beat period is defined as 16 ispclk cycles. A 16 cycle period was chosen to make the throttling independent of the actual clock ratio between ispclk and coreclk. Note that clock gating should be enabled when thermal throttling is enabled.
23:22	0h RW	**RSVD_23_22:** Reserved
21	0h RW	**DISABLE_ISM_IDLE_FREEZE:** DISABLE_ISM_IDLE_FREEZE: When IUNIT receive a RESET_WARN message from PUNIT, it will freeze the IOSF primary Idle State Machine (among other things), before sending an OK_TO_RESET message to PUNIT. 20	0h RW	**DISABLE_OCP_PHASE_ORDERING:** DISABLE_OCP_PHASE_ORDERING: By default, IUNIT will follow the OCP phase ordering protocol and wait until a write command is accepted before accepting the write data corresponding to that command. If the DISABLE_OCP_PHASE_ORDERING bit is set, the IUNIT wrapper will accept the write data independent of the write command.
19	0h RW	**ICACHE_CMD_WEIGHT:** ICACHE_CMD_WEIGHT: 0b = Requests from the OCP master port sending Icache miss traffic will win arbitration over requests from the OCP master port that sends pixel data traffic. 1b = Requests from the two OCP master interfaces will be accepted in a round robin fashion.
18:16	0h RW	**THERM_MASK:** THERM_MASK: This field determines the amount of thermal throttling applied to ispclk. The value of this field determines how many beat periods of ispclk are killed, where a beat period is defined as 16 ispclk cycles. A 16 cycle period was chosen to make the throttling independent of the actual clock ratio between ispclk and coreclk. 000 = No throttling; 001 = 12.5% throttling; 010 = 25% throttling; 011 = 37.5% throttling; 100 = 50% throttling; 101 = 62.5% throttling; 110 = 75% throttling; 111 = 87.5% throttling;
15:8	01h RW	**MID:** MIN_IDLE_DELAY: Minimum wait time after the rising edge of idle, before the clock gating state machine will start the sequence to gate ispclk. Range is 0 to 130 usec. Unit is 0.512 usec. Reset value of 8'h1 indicates MID = 0.512 usec.
7	0b RW	**RCOMPCLK_GATING_DISABLE:** 1 = Disable clock gating for rcompclk. 0 = Enable clock gating for rcompclk. Note: All clock gating is disabled by hardware while reset is asserted, regardless of the state of this field.

3:2	0h RW	**SRSE:** SOFT_RESET_SEQUENCE_ENABLE: If SRSE=2b00: When an IUNIT_RESET_WARN message is received from PUNIT, IUNIT will a) stop accepting requests on the IOSF primary interface, b) stop accepting new requests from the OCP master interface, c) wait until read data from all earlier read requests received from the OCP master interface have been returned by SSA, d) wait until SSA reads data for all earlier PFI write requests, and e) wait for all DPHY lanes to enter stop state (LP11), and then f) send an IUNIT_OK_TO_RESET posted message to PUNIT. If SRSE=2b01: When an IUNIT_RESET_WARN message is received from PUNIT, IUNIT will a) stop accepting requests on the IOSF primary interface, b) stop accepting new requests from the OCP master interface, c) wait until read data from all earlier read requests received from the OCP master interface have been returned by SSA, d) wait until SSA reads data for all earlier PFI write requests, and then e) send an IUNIT_OK_TO_RESET posted message to PUNIT.
