3.8.7 reg_SUBSYSTEMID_type (SUBSYSTEMID)—Offset 2Ch

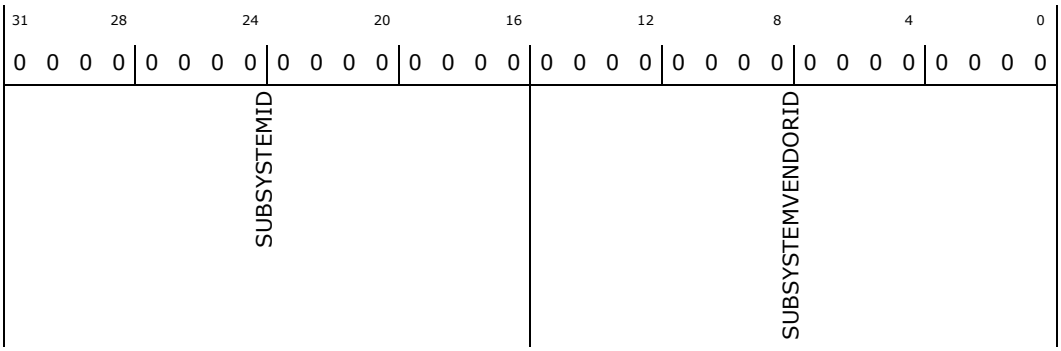
SUBSYSTEMID -Subsystem Vendor and Subsystem ID

Access Method

Type: PCI Configuration Register (Size: 32 bits)

SUBSYSTEMID: [B:0, D:16, F:0] + 2Ch

Default: 00000000h



Bit Range	Default & Access	Description
31:16	0000h RW/O	**SUBSYSTEMID:** Reserved.
15:0	0000h RW/O	**SUBSYSTEMVENDORID:** Reserved.

3.8.8 reg_EXPANSION_ROM_BASEADDR_type (EXPANSION_ROM_BASEADDR)—Offset 30h

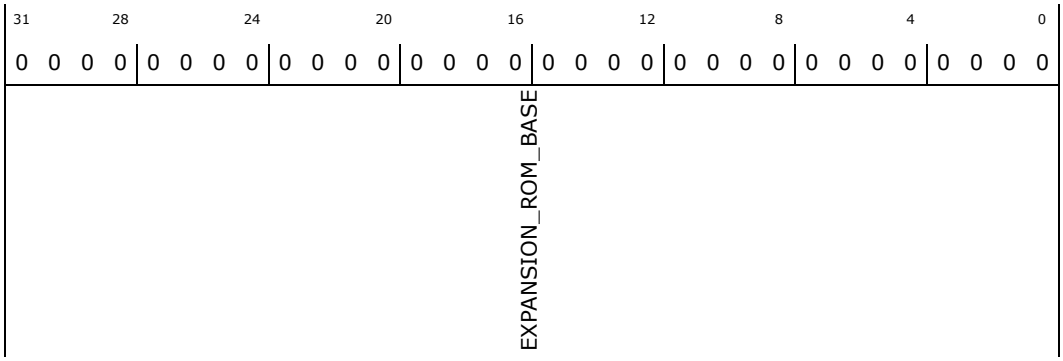
EXPANSION ROM base address

Access Method

Type: PCI Configuration Register (Size: 32 bits)

EXPANSION_ROM_BASEADDR: [B:0, D:16, F:0] + 30h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	00000000h RO	**EXPANSION_ROM_BASE:** Reserved.

3.8.9 reg_CAPABILITYPTR_type (CAPABILITYPTR)—Offset 34h

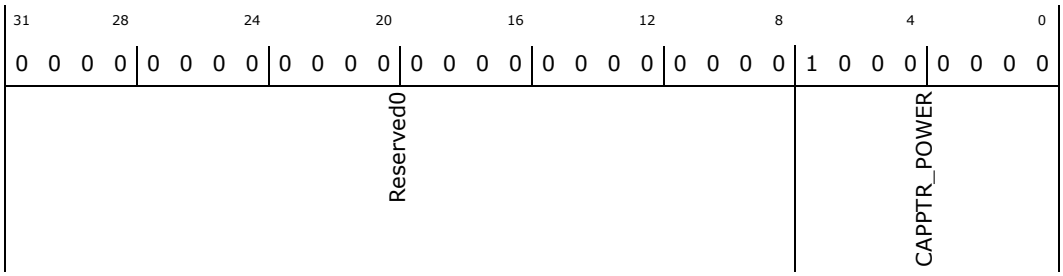
CAPABILITYPTR - Capabilities Pointer

Access Method

Type: PCI Configuration Register (Size: 32 bits)

CAPABILITYPTR: [B:0, D:16, F:0] + 34h

Default: 00000080h



Bit Range	Default & Access	Description

7:0	80h RO	**CAPPTR_POWER:** Reserved.

3.8.10 reg_INTERRUPTREG_type (INTERRUPTREG)—Offset 3Ch

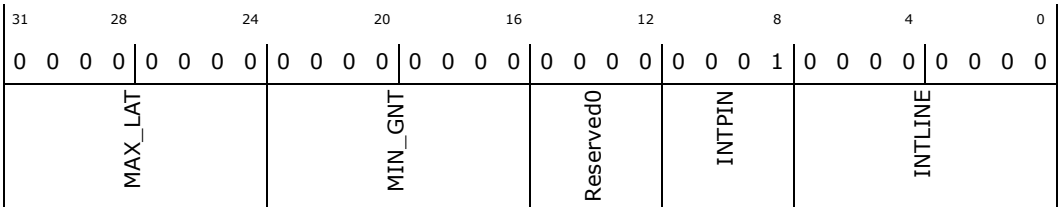
INTERRUPTREG - Interrupt Register

Access Method

Type: PCI Configuration Register (Size: 32 bits)

INTERRUPTREG: [B:0, D:16, F:0] + 3Ch

Default: 00000100h



Bit Range	Default & Access	Description

3.9.1 SDMA System Address Register (SYS_ADR)—Offset 0h

This register contains the physical system memory address used for DMA transfers

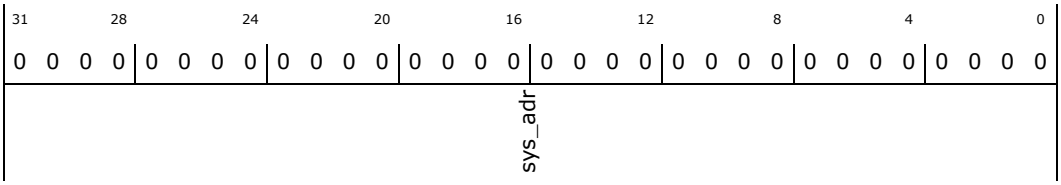
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SYS_ADR: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:16, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	00000000h RW	**SYS_ADR (sys_adr):** SDMA System Address This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at the every boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the most upper byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register.

3.9.2 Block Size Register (BLK_SIZE)—Offset 4h

This register is used to configure the number of bytes in a data block.

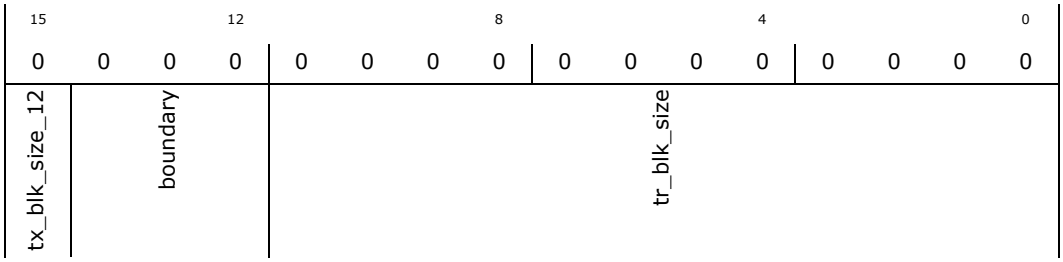
Access Method

Type: Memory Mapped I/O Register (Size: 16 bits)

BLK_SIZE: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:16, F:0] + 10h

Default: 0000h



Bit Range	Default & Access	Description
15	0b RW	**TX_BLK_SIZE_12 (tx_blk_size_12):** Transfer Block Size 12th bit. This bit is added to support 4Kb Data block transfer.

Bit Range	Default & Access	Description
14:12	000b RW	**BOUNDARY (boundary):** Host SDMA Buffer Boundary The large contiguous memory space may not be available in the virtual memory system. To perform long SDMA transfer, SDMA System Address register shall be updated at every system memory boundary during SDMA transfer. These bits specify the size of contiguous buffer in the system memory. The SDMA transfer shall wait at the every boundary specified by these fields and the Host Controller generates the DMA Interrupt to request the Host Driver to update the SDMA System Address register. At the end of transfer, the Host Controller may issue or may not issue DMA Interrupt. In particular, DMA Interrupt shall not be issued after Transfer Complete Interrupt is issued. In case of this register is set to 0 (buffer size = 4K bytes), lower 12-bit of byte address points data in the contiguous buffer and the upper 20-bit points the location of the buffer in the system memory. The SDMA transfer stops when the Host Controller detects carry out of the address from bit 11 to 12. These bits shall be supported when the SDMA Support in the Capabilities register is set to 1 and this function is active when the DMA Enable in the Transfer Mode register is set to 1. ADMA does not use this register. 000b - 4K bytes (Detects A11 carry out) 001b - 8K bytes (Detects A12 carry out) 010b - 16K Bytes (Detects A13 carry out) 011b - 32K Bytes (Detects A14 carry out) 100b - 64K bytes (Detects A15 carry out) 101b - 128K Bytes (Detects A16 carry out) 110b - 256K Bytes (Detects A17 carry out) 111b - 512K Bytes (Detects A18 carry out)
11:0	000h RW	**TR_BLK_SIZE (tr_blk_size):** Transfer Block Size This register specifies the block size of data transfers for CMD17, CMD18, CMD24, CMD25, and CMD53. Values ranging from 1 up to the maximum buffer size can be set. In case of memory, it shall be set up to 512 bytes (Refer to Implementation Note in Section 1.7.2). It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations shall be ignored. 0800h 2048 Bytes ??? ??? 0200h 512 Bytes 01FFh 511 Bytes ??? ??? 0004h 4 Bytes 0003h 3 Bytes 0002h 2 Bytes 0001h 1 Byte 0000h No data transfer

3.9.3 Block Count Register (BLK_COUNT)—Offset 6h

This register is used to configure the number of data blocks

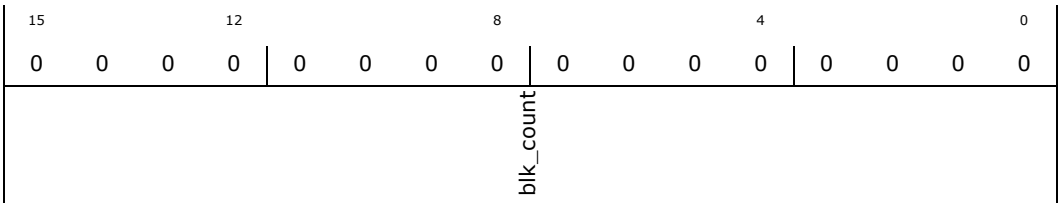
Access Method

Type: Memory Mapped I/O Register (Size: 16 bits)

BLK_COUNT: [BAR] + 6h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:16, F:0] + 10h

Default: 0000h



Bit Range	Default & Access	Description
15:0	0000h RW	**BLK_COUNT (blk_count):** Blocks Count For Current Transfer This register is enabled when Block Count Enable in the Transfer Mode register is set to 1 and is valid only for multiple block transfers

3.9.4 Argument Register (ARGUMENT)—Offset 8h

This register contains the SD Command Argument.

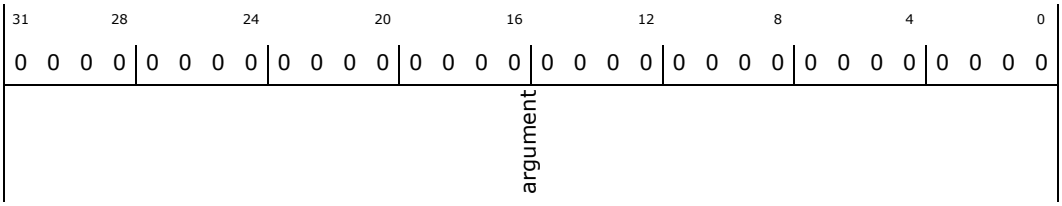
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

ARGUMENT: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:16, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**ARGUMENT (argument):** Command Argument The SD Command Argument is specified as bit39-8 of Command-Format in the Physical Layer Specification.

3.9.5 Transfer Mode Register (TX_MODE)—Offset Ch

Transfer Mode Register

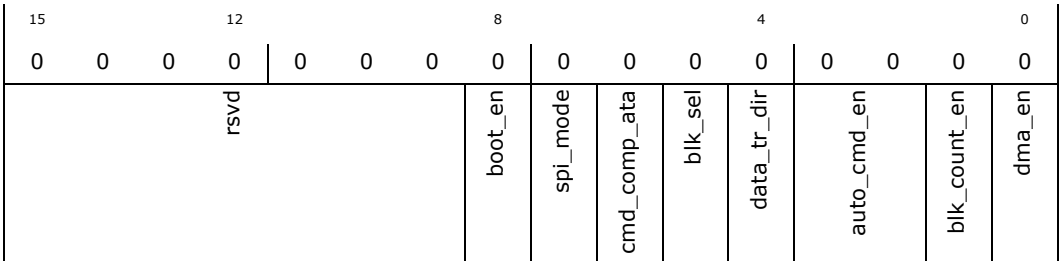
Access Method

Type: Memory Mapped I/O Register (Size: 16 bits)

TX_MODE: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:16, F:0] + 10h

Default: 0000h



Bit Range	Default & Access	Description
15:9	00h RO	**RSVD (rsvd):** Reserved
8	0b RW	**BOOT_EN (boot_en):** To start boot operation for MMC4.3 1 - To start boot mode 0 - Stop the boot read
7	0b RW	**SPI_MODE (spi_mode):** SPI mode enable bit. 1 - SPI mode 0 - SD mode
6	0b RW	**CMD_COMP_ATA (cmd_comp_ata):** Command Completion Signal Enable for CE-ATA Device. ???1??? - Device will send command completion Signal ???0??? - Device will not send command completion Signal
5	0b RW	**BLK_SEL (blk_sel):** Multi / Single Block Select This bit is set when issuing multiple-block transfer commands using DAT line. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (Refer to Table 2-8) 1 Multiple Block 0 Single Block
4	0b RW	**Data_TR_Dir (data_tr_dir):** Data Transfer Direction Select This bit defines the direction of DAT line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the SD Host Controller and it is set to 0 for all other commands. 1 Read (Card to Host) 0 Write (Host to Card)
3:2	0b RW	**AUTO_CMD_EN (auto_cmd_en):** This field determines use of auto command functions 00b - Auto Command Disabled 01b - Auto CMD12 Enable 10b - Auto CMD23 Enable 11b - Reserved
1	0b RW	**BLK_COUNT_EN (blk_count_en):** Block Count Enable This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the Block Count register is disabled, which is useful in executing an infinite transfer. (Refer to Table 2-8) If ADMA2 data transfer is more than 65535 blocks, this bit shall be set to 0. In this case, data transfer length is designated by Descriptor Table. 1 Enable 0 Disable
0	0b RW	**DMA_EN (dma_en):** DMA Enable This bit enables DMA functionality as described in section 1.4. DMA can be enabled only if it is supported as indicated in the Capabilities register. One of the DMA modes can be selected by DMA Select in the Host Control register. If DMA is not supported, this bit is meaningless and shall always read 0. If this bit is set to 1, a DMA operation shall begin when the Host Driver writes to the upper byte of Command register (00Fh). 1 DMA Data transfer 0 No data transfer or Non DMA data transfer

3.9.6 Command Register (CMD)—Offset Eh

Command Register

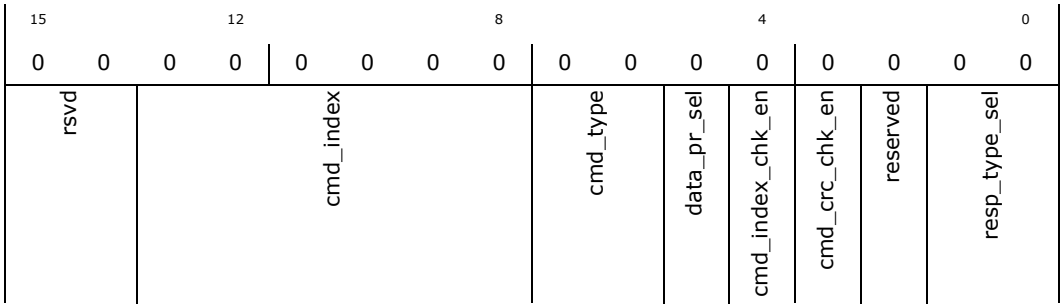
Access Method

Type: Memory Mapped I/O Register (Size: 16 bits)

CMD: [BAR] + Eh

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:16, F:0] + 10h

Default: 0000h



Bit Range	Default & Access	Description
15:14	0h RO	**RSVD (rsvd):** Reserved
13:8	0h RW	**CMD_INDEX (cmd_index):** Command Index These bits shall be set to the command number (CMD0-63, ACMD0-63) that is specified in bits 45-40 of the Command-Format in the Physical Layer Specification and SDIO Card Specification.
7:6	00b RW	**CMD_TYPE (cmd_type):** Command Type
5	0b RW	**DATA_PR_SEL (data_pr_sel):** Data Present Select This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following: (1) Commands using only CMD line (ex. CMD52). (2) Commands with no data transfer but using busy signal on DAT[0] line (R1b or R5b ex. CMD38) (3) Resume command 1 Data Present 0 No Data Present
4	0b RW	**CMD_INDEX_CHK_EN (cmd_index_chk_en):** Command Index Check Enable If this bit is set to 1, the Host Controller shall check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked. 1 Enable 0 Disable
3	0b RW	**CMD_CRC_CHK_EN (cmd_crc_chk_en):** Command CRC Check Enable If this bit is set to 1, the Host Controller shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The position of CRC field is determined according to the length of the response. (Refer to definition in D01-00 and Table 2-10 below.) 1 Enable 0 Disable
2	0b RO	**Reserved (reserved):** Reserved

3.11.1 SDMA System Address Register (SYS_ADR)—Offset 0h

This register contains the physical system memory address used for DMA transfers

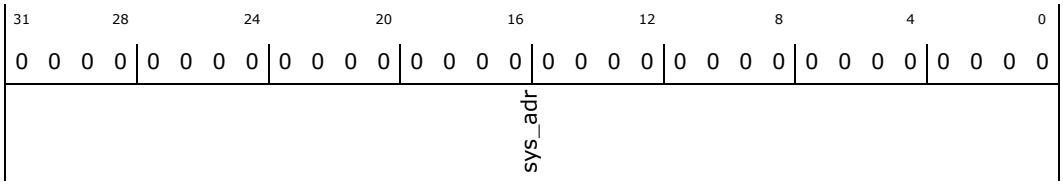
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SYS_ADR: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:17, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	00000000h RW	**SYS_ADR (sys_adr):** SDMA System Address This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at the every boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the most upper byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register.

3.11.2 Block Size Register (BLK_SIZE)—Offset 4h

This register is used to configure the number of bytes in a data block.

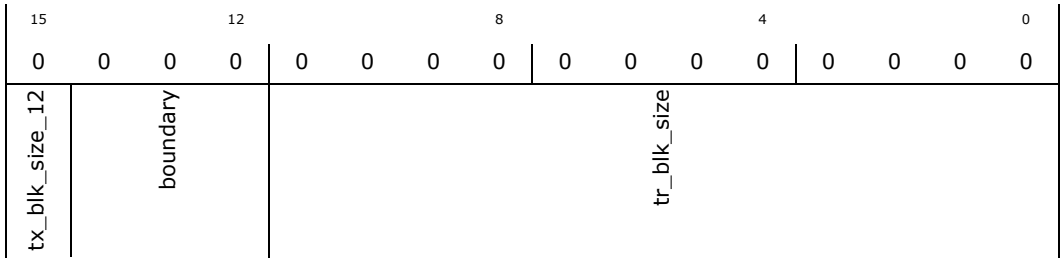
Access Method

Type: Memory Mapped I/O Register (Size: 16 bits)

BLK_SIZE: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:17, F:0] + 10h

Default: 0000h



Bit Range	Default & Access	Description
15	0b RW	**TX_BLK_SIZE_12 (tx_blk_size_12):** Transfer Block Size 12th bit. This bit is added to support 4Kb Data block transfer.

Bit Range	Default & Access	Description
14:12	000b RW	**BOUNDARY (boundary):** Host SDMA Buffer Boundary The large contiguous memory space may not be available in the virtual memory system. To perform long SDMA transfer, SDMA System Address register shall be updated at every system memory boundary during SDMA transfer. These bits specify the size of contiguous buffer in the system memory. The SDMA transfer shall wait at the every boundary specified by these fields and the Host Controller generates the DMA Interrupt to request the Host Driver to update the SDMA System Address register. At the end of transfer, the Host Controller may issue or may not issue DMA Interrupt. In particular, DMA Interrupt shall not be issued after Transfer Complete Interrupt is issued. In case of this register is set to 0 (buffer size = 4K bytes), lower 12-bit of byte address points data in the contiguous buffer and the upper 20-bit points the location of the buffer in the system memory. The SDMA transfer stops when the Host Controller detects carry out of the address from bit 11 to 12. These bits shall be supported when the SDMA Support in the Capabilities register is set to 1 and this function is active when the DMA Enable in the Transfer Mode register is set to 1. ADMA does not use this register. 000b - 4K bytes (Detects A11 carry out) 001b - 8K bytes (Detects A12 carry out) 010b - 16K Bytes (Detects A13 carry out) 011b - 32K Bytes (Detects A14 carry out) 100b - 64K bytes (Detects A15 carry out) 101b - 128K Bytes (Detects A16 carry out) 110b - 256K Bytes (Detects A17 carry out) 111b - 512K Bytes (Detects A18 carry out)
11:0	000h RW	**TR_BLK_SIZE (tr_blk_size):** Transfer Block Size This register specifies the block size of data transfers for CMD17, CMD18, CMD24, CMD25, and CMD53. Values ranging from 1 up to the maximum buffer size can be set. In case of memory, it shall be set up to 512 bytes (Refer to Implementation Note in Section 1.7.2). It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations shall be ignored. 0800h 2048 Bytes ??? ??? 0200h 512 Bytes 01FFh 511 Bytes ??? ??? 0004h 4 Bytes 0003h 3 Bytes 0002h 2 Bytes 0001h 1 Byte 0000h No data transfer

3.11.3 Block Count Register (BLK_COUNT)—Offset 6h

This register is used to configure the number of data blocks

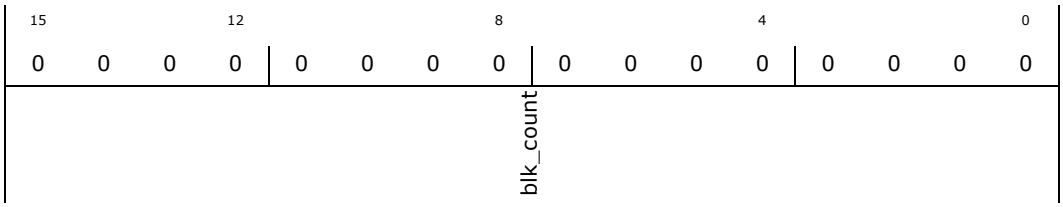
Access Method

Type: Memory Mapped I/O Register (Size: 16 bits)

BLK_COUNT: [BAR] + 6h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:17, F:0] + 10h

Default: 0000h



Bit Range	Default & Access	Description
15:0	0000h RW	**BLK_COUNT (blk_count):** Blocks Count For Current Transfer This register is enabled when Block Count Enable in the Transfer Mode register is set to 1 and is valid only for multiple block transfers

3.11.4 Argument Register (ARGUMENT)—Offset 8h

This register contains the SD Command Argument.

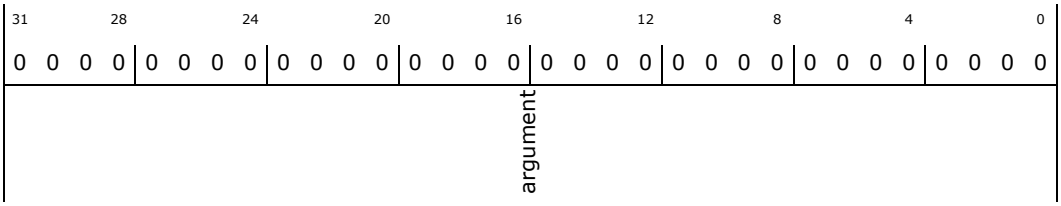
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

ARGUMENT: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:17, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**ARGUMENT (argument):** Command Argument The SD Command Argument is specified as bit39-8 of Command-Format in the Physical Layer Specification.

3.11.5 Transfer Mode Register (TX_MODE)—Offset Ch

Transfer Mode Register

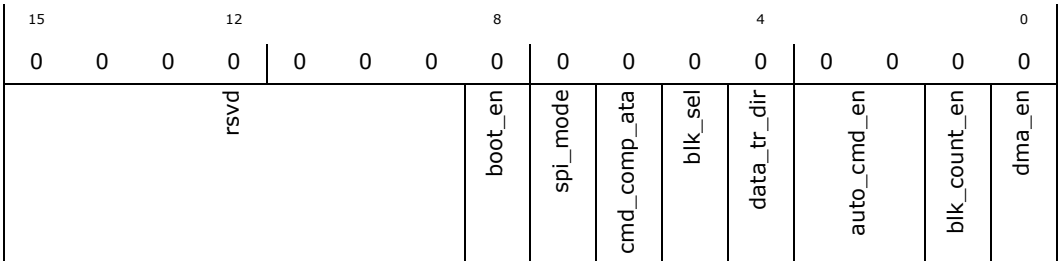
Access Method

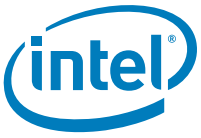
Type: Memory Mapped I/O Register (Size: 16 bits)

TX_MODE: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:17, F:0] + 10h

Default: 0000h





Bit Range	Default & Access	Description
15:9	00h RO	**RSVD (rsvd):** Reserved
8	0b RW	**BOOT_EN (boot_en):** To start boot operation for MMC4.3 1 - To start boot mode 0 - Stop the boot read
7	0b RW	**SPI_MODE (spi_mode):** SPI mode enable bit. 1 - SPI mode 0 - SD mode
6	0b RW	**CMD_COMP_ATA (cmd_comp_ata):** Command Completion Signal Enable for CE-ATA Device. ???1??? - Device will send command completion Signal ???0??? - Device will not send command completion Signal
5	0b RW	**BLK_SEL (blk_sel):** Multi / Single Block Select This bit is set when issuing multiple-block transfer commands using DAT line. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (Refer to Table 2-8) 1 Multiple Block 0 Single Block
4	0b RW	**Data_TR_Dir (data_tr_dir):** Data Transfer Direction Select This bit defines the direction of DAT line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the SD Host Controller and it is set to 0 for all other commands. 1 Read (Card to Host) 0 Write (Host to Card)
3:2	0b RW	**AUTO_CMD_EN (auto_cmd_en):** This field determines use of auto command functions 00b - Auto Command Disabled 01b - Auto CMD12 Enable 10b - Auto CMD23 Enable 11b - Reserved
1	0b RW	**BLK_COUNT_EN (blk_count_en):** Block Count Enable This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the Block Count register is disabled, which is useful in executing an infinite transfer. (Refer to Table 2-8) If ADMA2 data transfer is more than 65535 blocks, this bit shall be set to 0. In this case, data transfer length is designated by Descriptor Table. 1 Enable 0 Disable
0	0b RW	**DMA_EN (dma_en):** DMA Enable This bit enables DMA functionality as described in section 1.4. DMA can be enabled only if it is supported as indicated in the Capabilities register. One of the DMA modes can be selected by DMA Select in the Host Control register. If DMA is not supported, this bit is meaningless and shall always read 0. If this bit is set to 1, a DMA operation shall begin when the Host Driver writes to the upper byte of Command register (00Fh). 1 DMA Data transfer 0 No data transfer or Non DMA data transfer

3.11.6 Command Register (CMD)—Offset Eh

Command Register

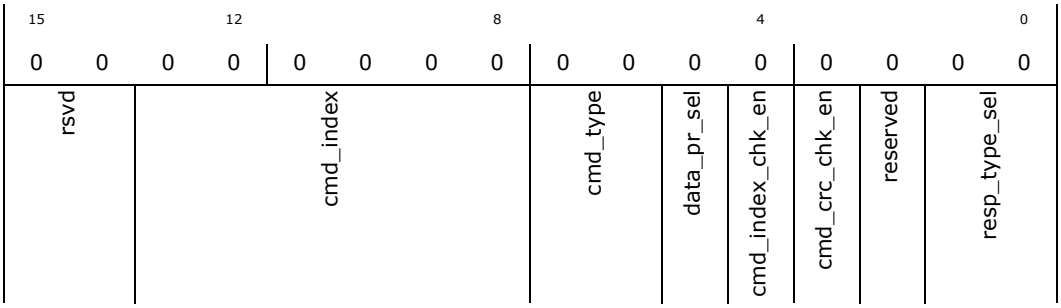
Access Method

Type: Memory Mapped I/O Register (Size: 16 bits)

CMD: [BAR] + Eh

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:17, F:0] + 10h

Default: 0000h



Bit Range	Default & Access	Description
15:14	0h RO	**RSVD (rsvd):** Reserved
13:8	0h RW	**CMD_INDEX (cmd_index):** Command Index These bits shall be set to the command number (CMD0-63, ACMD0-63) that is specified in bits 45-40 of the Command-Format in the Physical Layer Specification and SDIO Card Specification.
7:6	00b RW	**CMD_TYPE (cmd_type):** Command Type
5	0b RW	**DATA_PR_SEL (data_pr_sel):** Data Present Select This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following: (1) Commands using only CMD line (ex. CMD52). (2) Commands with no data transfer but using busy signal on DAT[0] line (R1b or R5b ex. CMD38) (3) Resume command 1 Data Present 0 No Data Present
4	0b RW	**CMD_INDEX_CHK_EN (cmd_index_chk_en):** Command Index Check Enable If this bit is set to 1, the Host Controller shall check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked. 1 Enable 0 Disable
3	0b RW	**CMD_CRC_CHK_EN (cmd_crc_chk_en):** Command CRC Check Enable If this bit is set to 1, the Host Controller shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The position of CRC field is determined according to the length of the response. (Refer to definition in D01-00 and Table 2-10 below.) 1 Enable 0 Disable
2	0b RO	**Reserved (reserved):** Reserved
1:0	0h RW	**RESP_TYPE_SEL (resp_type_sel):** Response Type Select 00 No Response 01 Response Length 136 10 Response Length 48 11 Response Length 48 check Busy after response

3.11.7 Response Register0 (RESPONSE0)—Offset 10h

This register is used to store responses from SD cards

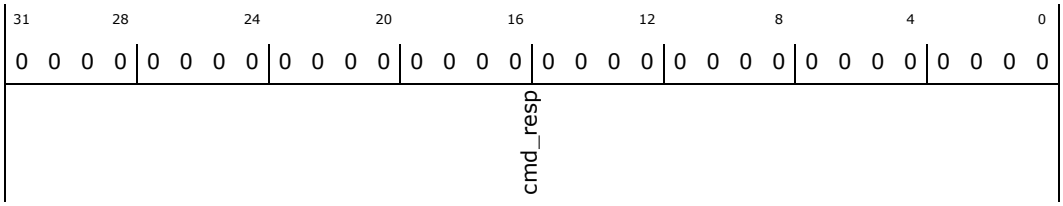
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

RESPONSE0: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:17, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RO	**CMD_RESP0 (cmd_resp):** Command Response The Table 2-12 describes the mapping of command responses from the SD Bus to this register for each response type. In the table, R[] refers to a bit range within the response data as transmitted on the SD Bus, REP[] refers to a bit range within the Response register

3.11.8 Response Register2 (RESPONSE2)—Offset 14h

This register is used to store responses from SD cards

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

RESPONSE2: [BAR] + 14h

BAR Type: PCI Configuration Register (Size: 32 bits)

31	0b RW	**PRESET_VALUE (preset_value):** Host Controller Version 3.00 supports this bit. As the operating SDCLK frequency and I/O driver strength depend on the Host System implementation, it is difficult to determine these parameters in the Standard Host Driver. When Preset Value Enable is set to automatic This bit enables the functions defined in the Preset Value registers. 1 Automatic Selection by Preset Value are Enabled 0 SDCLK and Driver Strength are controlled by Host Driver If this bit is set to 0, SDCLK Frequency Select, Clock Generator Select in the Clock Control register and Driver Strength Select in Host Control 2 register are set by Host Driver. If this bit is set to 1, SDCLK Frequency Select, Clock Generator Select in the Clock Control register and Driver Strength Select in Host Control 2 register are set by Host Controller as specified in the Preset Value registers.

Bit Range	Default & Access	Description
30	0b RW	**ASYNC_INT (async_int):** This bit can be set to 1 if a card support asynchronous interrupt and Asynchronous Interrupt Support is set to 1 in the Capabilities register. Asynchronous interrupt is effective when DAT[1] interrupt is used in 4-bit SD mode (and zero is set to Interrupt Pin Select in the Shared Bus Control register). If this bit is set to 1, the Host Driver can stop the SDCLK during asynchronous interrupt period to save power. During this period, the Host Controller continues to deliver Card Interrupt to the host when it is asserted by the Card. 1 Enabled 0 Disabled

3.13.1 SDMA System Address Register (SYS_ADR)—Offset 0h

This register contains the physical system memory address used for DMA transfers

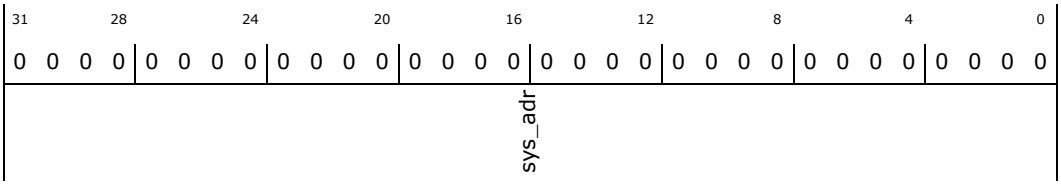
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SYS_ADR: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:18, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	00000000h RW	**SYS_ADR (sys_adr):** SDMA System Address This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at the every boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the most upper byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register.

3.13.2 Block Size Register (BLK_SIZE)—Offset 4h

This register is used to configure the number of bytes in a data block.

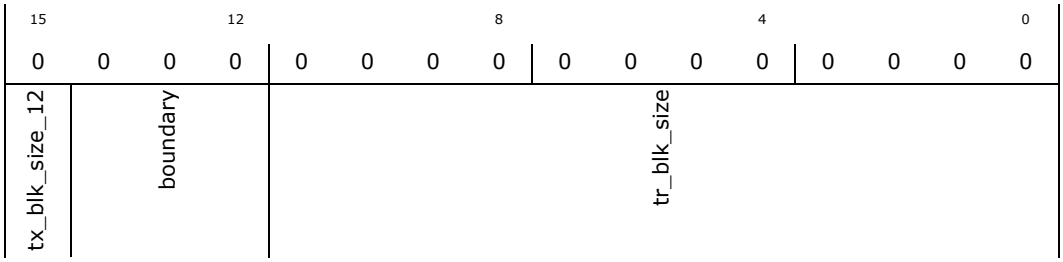
Access Method

Type: Memory Mapped I/O Register (Size: 16 bits)

BLK_SIZE: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:18, F:0] + 10h

Default: 0000h



Bit Range	Default & Access	Description
15	0b RW	**TX_BLK_SIZE_12 (tx_blk_size_12):** Transfer Block Size 12th bit. This bit is added to support 4Kb Data block transfer.

Bit Range	Default & Access	Description
14:12	000b RW	**BOUNDARY (boundary):** Host SDMA Buffer Boundary The large contiguous memory space may not be available in the virtual memory system. To perform long SDMA transfer, SDMA System Address register shall be updated at every system memory boundary during SDMA transfer. These bits specify the size of contiguous buffer in the system memory. The SDMA transfer shall wait at the every boundary specified by these fields and the Host Controller generates the DMA Interrupt to request the Host Driver to update the SDMA System Address register. At the end of transfer, the Host Controller may issue or may not issue DMA Interrupt. In particular, DMA Interrupt shall not be issued after Transfer Complete Interrupt is issued. In case of this register is set to 0 (buffer size = 4K bytes), lower 12-bit of byte address points data in the contiguous buffer and the upper 20-bit points the location of the buffer in the system memory. The SDMA transfer stops when the Host Controller detects carry out of the address from bit 11 to 12. These bits shall be supported when the SDMA Support in the Capabilities register is set to 1 and this function is active when the DMA Enable in the Transfer Mode register is set to 1. ADMA does not use this register. 000b - 4K bytes (Detects A11 carry out) 001b - 8K bytes (Detects A12 carry out) 010b - 16K Bytes (Detects A13 carry out) 011b - 32K Bytes (Detects A14 carry out) 100b - 64K bytes (Detects A15 carry out) 101b - 128K Bytes (Detects A16 carry out) 110b - 256K Bytes (Detects A17 carry out) 111b - 512K Bytes (Detects A18 carry out)
11:0	000h RW	**TR_BLK_SIZE (tr_blk_size):** Transfer Block Size This register specifies the block size of data transfers for CMD17, CMD18, CMD24, CMD25, and CMD53. Values ranging from 1 up to the maximum buffer size can be set. In case of memory, it shall be set up to 512 bytes (Refer to Implementation Note in Section 1.7.2). It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations shall be ignored. 0800h 2048 Bytes ??? ??? 0200h 512 Bytes 01FFh 511 Bytes ??? ??? 0004h 4 Bytes 0003h 3 Bytes 0002h 2 Bytes 0001h 1 Byte 0000h No data transfer

3.13.3 Block Count Register (BLK_COUNT)—Offset 6h

This register is used to configure the number of data blocks

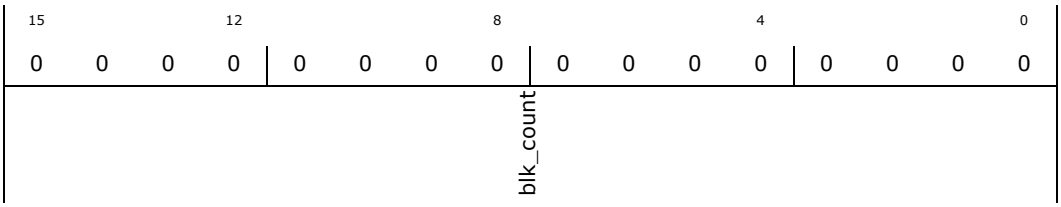
Access Method

Type: Memory Mapped I/O Register (Size: 16 bits)

BLK_COUNT: [BAR] + 6h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:18, F:0] + 10h

Default: 0000h



Bit Range	Default & Access	Description
15:0	0000h RW	**BLK_COUNT (blk_count):** Blocks Count For Current Transfer This register is enabled when Block Count Enable in the Transfer Mode register is set to 1 and is valid only for multiple block transfers

3.13.4 Argument Register (ARGUMENT)—Offset 8h

This register contains the SD Command Argument.

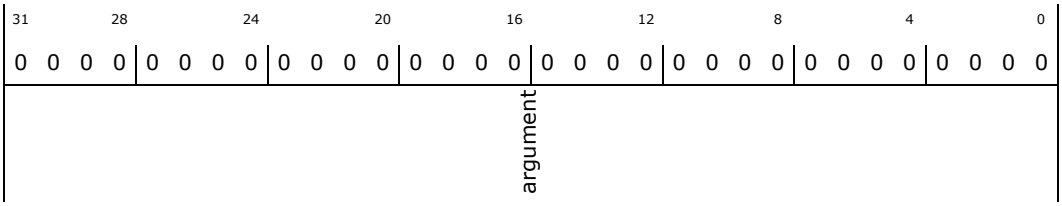
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

ARGUMENT: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:18, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**ARGUMENT (argument):** Command Argument The SD Command Argument is specified as bit39-8 of Command-Format in the Physical Layer Specification.

3.13.5 Transfer Mode Register (TX_MODE)—Offset Ch

Transfer Mode Register

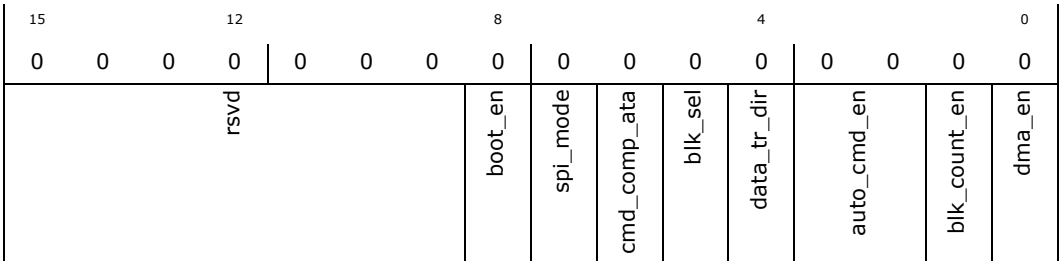
Access Method

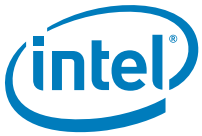
Type: Memory Mapped I/O Register (Size: 16 bits)

TX_MODE: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:18, F:0] + 10h

Default: 0000h





Bit Range	Default & Access	Description
15:9	00h RO	**RSVD (rsvd):** Reserved
8	0b RW	**BOOT_EN (boot_en):** To start boot operation for MMC4.3 1 - To start boot mode 0 - Stop the boot read
7	0b RW	**SPI_MODE (spi_mode):** SPI mode enable bit. 1 - SPI mode 0 - SD mode
6	0b RW	**CMD_COMP_ATA (cmd_comp_ata):** Command Completion Signal Enable for CE-ATA Device. ???1??? - Device will send command completion Signal ???0??? - Device will not send command completion Signal
5	0b RW	**BLK_SEL (blk_sel):** Multi / Single Block Select This bit is set when issuing multiple-block transfer commands using DAT line. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (Refer to Table 2-8) 1 Multiple Block 0 Single Block
4	0b RW	**Data_TR_Dir (data_tr_dir):** Data Transfer Direction Select This bit defines the direction of DAT line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the SD Host Controller and it is set to 0 for all other commands. 1 Read (Card to Host) 0 Write (Host to Card)
3:2	0b RW	**AUTO_CMD_EN (auto_cmd_en):** This field determines use of auto command functions 00b - Auto Command Disabled 01b - Auto CMD12 Enable 10b - Auto CMD23 Enable 11b - Reserved
1	0b RW	**BLK_COUNT_EN (blk_count_en):** Block Count Enable This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the Block Count register is disabled, which is useful in executing an infinite transfer. (Refer to Table 2-8) If ADMA2 data transfer is more than 65535 blocks, this bit shall be set to 0. In this case, data transfer length is designated by Descriptor Table. 1 Enable 0 Disable
0	0b RW	**DMA_EN (dma_en):** DMA Enable This bit enables DMA functionality as described in section 1.4. DMA can be enabled only if it is supported as indicated in the Capabilities register. One of the DMA modes can be selected by DMA Select in the Host Control register. If DMA is not supported, this bit is meaningless and shall always read 0. If this bit is set to 1, a DMA operation shall begin when the Host Driver writes to the upper byte of Command register (00Fh). 1 DMA Data transfer 0 No data transfer or Non DMA data transfer

3.13.6 Command Register (CMD)—Offset Eh

Command Register

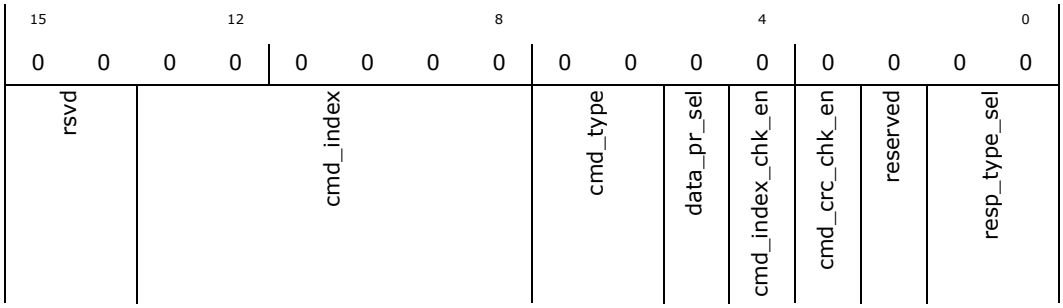
Access Method

Type: Memory Mapped I/O Register (Size: 16 bits)

CMD: [BAR] + Eh

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:18, F:0] + 10h

Default: 0000h



Bit Range	Default & Access	Description
15:14	0h RO	**RSVD (rsvd):** Reserved
13:8	0h RW	**CMD_INDEX (cmd_index):** Command Index These bits shall be set to the command number (CMD0-63, ACMD0-63) that is specified in bits 45-40 of the Command-Format in the Physical Layer Specification and SDIO Card Specification.
7:6	00b RW	**CMD_TYPE (cmd_type):** Command Type
5	0b RW	**DATA_PR_SEL (data_pr_sel):** Data Present Select This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following: (1) Commands using only CMD line (ex. CMD52). (2) Commands with no data transfer but using busy signal on DAT[0] line (R1b or R5b ex. CMD38) (3) Resume command 1 Data Present 0 No Data Present
4	0b RW	**CMD_INDEX_CHK_EN (cmd_index_chk_en):** Command Index Check Enable If this bit is set to 1, the Host Controller shall check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked. 1 Enable 0 Disable
3	0b RW	**CMD_CRC_CHK_EN (cmd_crc_chk_en):** Command CRC Check Enable If this bit is set to 1, the Host Controller shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The position of CRC field is determined according to the length of the response. (Refer to definition in D01-00 and Table 2-10 below.) 1 Enable 0 Disable

3.15.1 SDMA System Address Register (SYS_ADR)—Offset 0h

This register contains the physical system memory address used for DMA transfers

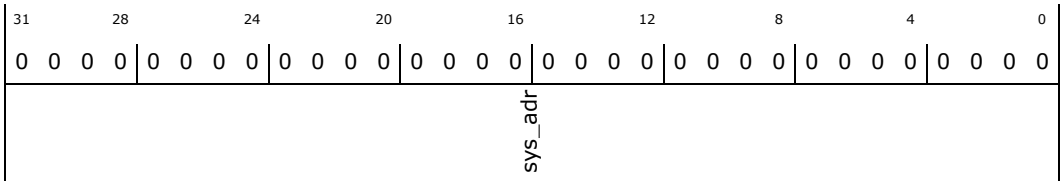
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SYS_ADR: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:23, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	00000000h RW	**SYS_ADR (sys_adr):** SDMA System Address This register contains the system memory address for a SDMA transfer. When the Host Controller stops a SDMA transfer, this register shall point to the system address of the next contiguous data position. It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value. The Host Driver shall initialize this register before starting a SDMA transaction. After SDMA has stopped, the next system address of the next contiguous data position can be read from this register. The SDMA transfer waits at the every boundary specified by the Host SDMA Buffer Boundary in the Block Size register. The Host Controller generates DMA Interrupt to request the Host Driver to update this register. The Host Driver sets the next system address of the next data position to this register. When the most upper byte of this register (003h) is written, the Host Controller restarts the SDMA transfer. When restarting SDMA by the Resume command or by setting Continue Request in the Block Gap Control register, the Host Controller shall start at the next contiguous address stored here in the SDMA System Address register. ADMA does not use this register.

3.15.2 Block Size Register (BLK_SIZE)—Offset 4h

This register is used to configure the number of bytes in a data block.

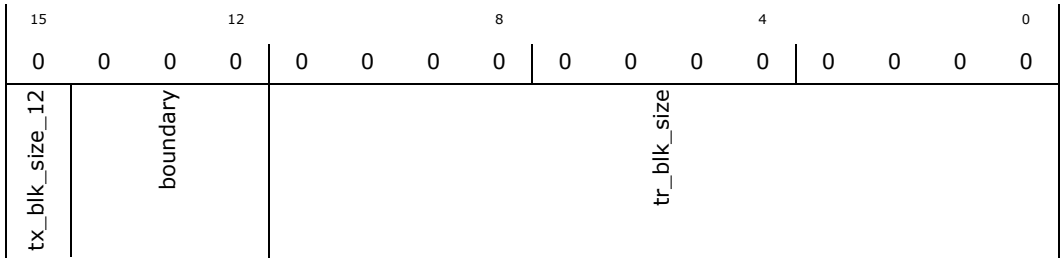
Access Method

Type: Memory Mapped I/O Register (Size: 16 bits)

BLK_SIZE: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:23, F:0] + 10h

Default: 0000h



Bit Range	Default & Access	Description
15	0b RW	**TX_BLK_SIZE_12 (tx_blk_size_12):** Transfer Block Size 12th bit. This bit is added to support 4Kb Data block transfer.

Bit Range	Default & Access	Description
14:12	000b RW	**BOUNDARY (boundary):** Host SDMA Buffer Boundary The large contiguous memory space may not be available in the virtual memory system. To perform long SDMA transfer, SDMA System Address register shall be updated at every system memory boundary during SDMA transfer. These bits specify the size of contiguous buffer in the system memory. The SDMA transfer shall wait at the every boundary specified by these fields and the Host Controller generates the DMA Interrupt to request the Host Driver to update the SDMA System Address register. At the end of transfer, the Host Controller may issue or may not issue DMA Interrupt. In particular, DMA Interrupt shall not be issued after Transfer Complete Interrupt is issued. In case of this register is set to 0 (buffer size = 4K bytes), lower 12-bit of byte address points data in the contiguous buffer and the upper 20-bit points the location of the buffer in the system memory. The SDMA transfer stops when the Host Controller detects carry out of the address from bit 11 to 12. These bits shall be supported when the SDMA Support in the Capabilities register is set to 1 and this function is active when the DMA Enable in the Transfer Mode register is set to 1. ADMA does not use this register. 000b - 4K bytes (Detects A11 carry out) 001b - 8K bytes (Detects A12 carry out) 010b - 16K Bytes (Detects A13 carry out) 011b - 32K Bytes (Detects A14 carry out) 100b - 64K bytes (Detects A15 carry out) 101b - 128K Bytes (Detects A16 carry out) 110b - 256K Bytes (Detects A17 carry out) 111b - 512K Bytes (Detects A18 carry out)
11:0	000h RW	**TR_BLK_SIZE (tr_blk_size):** Transfer Block Size This register specifies the block size of data transfers for CMD17, CMD18, CMD24, CMD25, and CMD53. Values ranging from 1 up to the maximum buffer size can be set. In case of memory, it shall be set up to 512 bytes (Refer to Implementation Note in Section 1.7.2). It can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations shall be ignored. 0800h 2048 Bytes ??? ??? 0200h 512 Bytes 01FFh 511 Bytes ??? ??? 0004h 4 Bytes 0003h 3 Bytes 0002h 2 Bytes 0001h 1 Byte 0000h No data transfer

3.15.3 Block Count Register (BLK_COUNT)—Offset 6h

This register is used to configure the number of data blocks

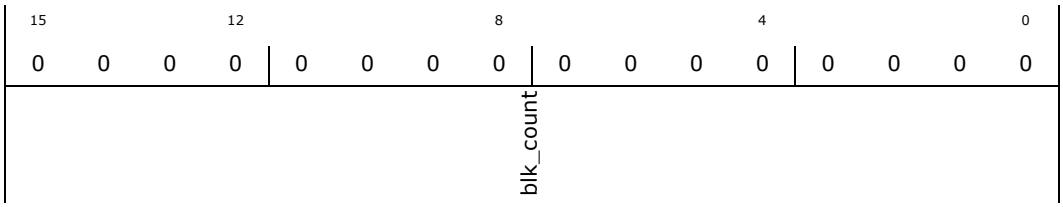
Access Method

Type: Memory Mapped I/O Register (Size: 16 bits)

BLK_COUNT: [BAR] + 6h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:23, F:0] + 10h

Default: 0000h



Bit Range	Default & Access	Description
15:0	0000h RW	**BLK_COUNT (blk_count):** Blocks Count For Current Transfer This register is enabled when Block Count Enable in the Transfer Mode register is set to 1 and is valid only for multiple block transfers

3.15.4 Argument Register (ARGUMENT)—Offset 8h

This register contains the SD Command Argument.

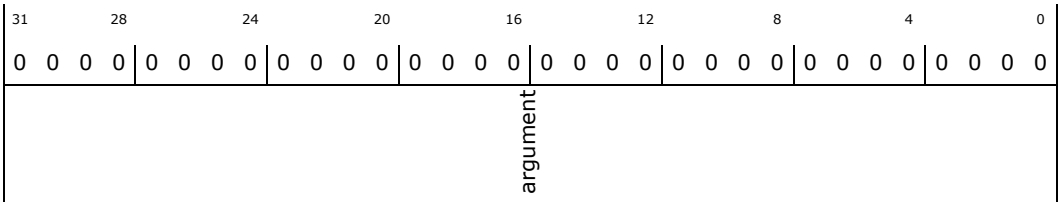
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

ARGUMENT: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:23, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**ARGUMENT (argument):** Command Argument The SD Command Argument is specified as bit39-8 of Command-Format in the Physical Layer Specification.

3.15.5 Transfer Mode Register (TX_MODE)—Offset Ch

Transfer Mode Register

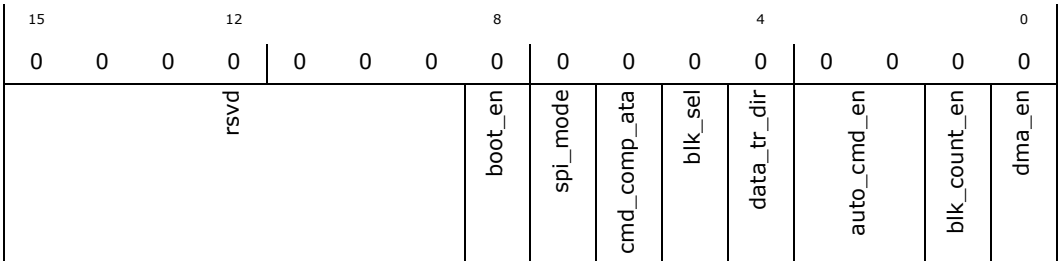
Access Method

Type: Memory Mapped I/O Register (Size: 16 bits)

TX_MODE: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:23, F:0] + 10h

Default: 0000h



Bit Range	Default & Access	Description
15:9	00h RO	**RSVD (rsvd):** Reserved
8	0b RW	**BOOT_EN (boot_en):** To start boot operation for MMC4.3 1 - To start boot mode 0 - Stop the boot read
7	0b RW	**SPI_MODE (spi_mode):** SPI mode enable bit. 1 - SPI mode 0 - SD mode
6	0b RW	**CMD_COMP_ATA (cmd_comp_ata):** Command Completion Signal Enable for CE-ATA Device. ???1??? - Device will send command completion Signal ???0??? - Device will not send command completion Signal
5	0b RW	**BLK_SEL (blk_sel):** Multi / Single Block Select This bit is set when issuing multiple-block transfer commands using DAT line. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (Refer to Table 2-8) 1 Multiple Block 0 Single Block
4	0b RW	**Data_TR_Dir (data_tr_dir):** Data Transfer Direction Select This bit defines the direction of DAT line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the SD Host Controller and it is set to 0 for all other commands. 1 Read (Card to Host) 0 Write (Host to Card)
3:2	0b RW	**AUTO_CMD_EN (auto_cmd_en):** This field determines use of auto command functions 00b - Auto Command Disabled 01b - Auto CMD12 Enable 10b - Auto CMD23 Enable 11b - Reserved
1	0b RW	**BLK_COUNT_EN (blk_count_en):** Block Count Enable This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the Block Count register is disabled, which is useful in executing an infinite transfer. (Refer to Table 2-8) If ADMA2 data transfer is more than 65535 blocks, this bit shall be set to 0. In this case, data transfer length is designated by Descriptor Table. 1 Enable 0 Disable
0	0b RW	**DMA_EN (dma_en):** DMA Enable This bit enables DMA functionality as described in section 1.4. DMA can be enabled only if it is supported as indicated in the Capabilities register. One of the DMA modes can be selected by DMA Select in the Host Control register. If DMA is not supported, this bit is meaningless and shall always read 0. If this bit is set to 1, a DMA operation shall begin when the Host Driver writes to the upper byte of Command register (00Fh). 1 DMA Data transfer 0 No data transfer or Non DMA data transfer

3.15.6 Command Register (CMD)—Offset Eh

Command Register

Access Method

Type: Memory Mapped I/O Register (Size: 16 bits)

Bit Range	Default & Access	Description
31	0b RW	**PRESET_VALUE (preset_value):** Host Controller Version 3.00 supports this bit. As the operating SDCLK frequency and I/O driver strength depend on the Host System implementation, it is difficult to determine these parameters in the Standard Host Driver. When Preset Value Enable is set to automatic This bit enables the functions defined in the Preset Value registers. 1 Automatic Selection by Preset Value are Enabled 0 SDCLK and Driver Strength are controlled by Host Driver If this bit is set to 0, SDCLK Frequency Select, Clock Generator Select in the Clock Control register and Driver Strength Select in Host Control 2 register are set by Host Driver. If this bit is set to 1, SDCLK Frequency Select, Clock Generator Select in the Clock Control register and Driver Strength Select in Host Control 2 register are set by Host Controller as specified in the Preset Value registers.

Bit Range	Default & Access	Description
30	0b RW	**ASYNC_INT (async_int):** This bit can be set to 1 if a card support asynchronous interrupt and Asynchronous Interrupt Support is set to 1 in the Capabilities register. Asynchronous interrupt is effective when DAT[1] interrupt is used in 4-bit SD mode (and zero is set to Interrupt Pin Select in the Shared Bus Control register). If this bit is set to 1, the Host Driver can stop the SDCLK during asynchronous interrupt period to save power. During this period, the Host Controller continues to deliver Card Interrupt to the host when it is asserted by the Card. 1 Enabled 0 Disabled

3.16.2 Command and Device Status (CMD_STS)—Offset 4h

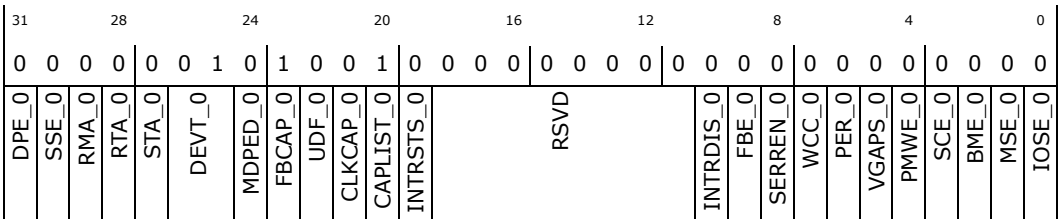
Access Method

Type: PCI Configuration Register (Size: 32 bits)

CMD_STS: [B:0, D:29, F:0] + 4h

Power Well: Core

Default: 02900000h



Bit Range	Default & Access	Description
31	0b RWC	**Detected Parity Error (DPE_0):** This bit is set whenever a parity error is seen on the internal interface to the USB2 host controller, regardless of the setting of bit 6 or bit 8 in the Command register or any other conditions. Software clears this bit by writing a '1' to this bit location.
30	0b RWC	**Signaled System Error (SSE_0):** This bit is set whenever it signals SERR# (internally). The SERR_EN bit (bit 8 in the Command Register) must be 1 for this bit to be set. The following conditions can cause the generation of SERR#: a parity error is seen on address, command, or data (if the data was targeting the EHC) on the internal interface to the USB2 host controller due to a parity error on the system interface and bit 6 of the Command register is set to 1. An EHC-initiated memory read results in a completion packet with a status other than successful on the system interface (if SERR on Aborts Enable is also set) Software clears this bit by writing a '1' to this bit location.

Bit Range	Default & Access	Description
29	0b RWC	**Received Master-Abort Status (RMA_0):** This bit is set when USB2, as a master, receives a master-abort status on a memory access. This is treated as a Host Error and halts the DMA engines. This event can optionally generate an SERR# by setting the SERR# Enable bit and the SERR on Aborts Enable (bit 3, offset 84h). Software clears this bit by writing a '1' to this bit location.
28	0b RWC	**Received Target Abort Status (RTA_0):** This bit is set when USB2, as a master, receives a target abort status on a memory access. This is treated as a Host Error and halts the DMA engines. This event can optionally generate an SERR# by setting the SERR# Enable bit and the SERR on Aborts Enable (bit 3, offset 84h). Software clears this bit by writing a '1' to this bit location.
27	0b RO	**Signaled Target-Abort Status (STA_0):** This bit is used to indicate when the USB2 function responds to a cycle with a target abort. There is no reason for this to happen, so this bit will be hard-wired to '0'. Read-Only
26:25	01b RO	**DEVSEL# Timing Status (DEVT_0):** This 2-bit field defines the timing for DEVSEL# assertion. Read-Only.
24	0b RWC	**Master Data Parity Error Detected (MDPED_0):** This bit is set whenever a data parity error is detected on a USB2 read completion packet on the internal interface to the USB2 host controller and bit 6 of the Command register is set to 1. Software clears this bit by writing a '1' to this bit location.
23	1b RO	**Fast Back-to-Back Capable (FBCAP_0):** Reserved as '1'.
22	0b RO	**User Definable Features (UDF_0):** Reserved as '0'
21	0b RO	**66 MHz Capable (CLKCAP_0):** Reserved as '0'
20	1b RO	**Capabilities List (CAPLIST_0):** Hardwired to '1' indicating that offset 34h contains a valid capabilities pointer.
19	0b RO	**Interrupt Status (INTRSTS_0):** This read-only bit reflects the state of this function's interrupt at the input of the enable/disable logic. This bit is a 1 when the interrupt is asserted. This bit will be 0 when the interrupt is deasserted. The value reported in this bit is independent of the value in the Interrupt Enable bit.
18:11	00000000b RO	**Reserved (RSVD):** Reserved.
10	0b RW	**Interrupt Disable (INTRDIS_0):** When cleared to '0', the function is capable of generating interrupts. When '1', the function can not generate its interrupt to the interrupt controller. Note that the corresponding Interrupt Status bit is not affected by the interrupt enable. This bit defaults to '0'. This bit is added as part of the PCI 2.3 Specification.
9	0b RO	**Fast Back to Back Enable (FBE_0):** Reserved as '0'.
8	0b RW	**SERR# Enable (SERREN_0):** on a memory read completion (if SERR on Aborts Enable is also set) Detection of an address or command parity error and the Parity Error Response bit is setDetection of a data parity error (when the data is going to the EHC) and the Parity Error Response bit is set
7	0b RO	**Wait Cycle Control (WCC_0):** Reserved as '0'.

Bit Range	Default & Access	Description
6	0b RW	**Parity Error Response (PER_0):** When set to 1, the USB2 Host Controller will check for correct parity (on its internal interface) and halt operation when bad parity is detected during the data phase as recommended by the EHCI specification. If it detects bad parity on the address or command phases when this bit is set to 1, the host controller does not take the cycle, halts the host controller (if currently not halted) and sets the host system error bit in the USBSTS register. Note that this applies to both requests and completions from the system interface. See section 9.19.2.4 for information regarding parity errors detected by the Prefetch DMA Engine. This bit must be set in order for the parity errors to generate SERR#.
5	0b RO	**VGA Palette Snoop (VGAPS_0):** Reserved as '0'
4	0b RO	**Postable Memory Write Enable (PMWE_0):** Reserved as '0'
3	0b RO	**Special Cycle Enable (SCE_0):** Reserved as '0'
2	0b RW	**Bus Master Enable (BME_0):** When set, bus mastering from EHCI is allowed, and will generate memory reads and writes for USB transfers. Notes on the EHC implementation: - Writes to change this bit occur immediately. Specifically, a write followed by a read will return the updated value. - When the BME bit is changed from 1 to 0, the EHC will cease accessing main memory within 2 microframes (250 usec). During this time, any number of reads and/or writes to memory may occur. - Clearing the BME bit shuts down the EHC DMA engines in the same manner that clearing the Run/Stop does. However, the schedule status bits and the HCHalted bit do not change based on the BME value.
1	0b RW	**Memory Space Enable (MSE_0):** This bit controls access to the USB2 Memory Space registers. If this bit is set, accesses to the USB2 registers are enabled. The Base Address register for USB2 should be programmed before this bit is set.
0	0b RO	**I/O Space Enable (IOSE_0):** Reserved as '0'.

3.16.3 Revision ID and Programming Interface and Sub/Base Class Code (RID_PI_CC)—Offset 8h

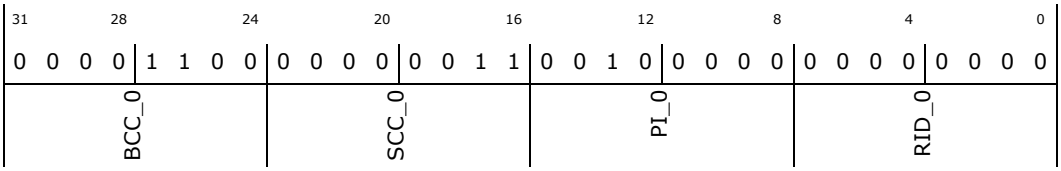
Access Method

Type: PCI Configuration Register (Size: 32 bits)

RID_PI_CC: [B:0, D:29, F:0] + 8h

Power Well: Core

Default: 0C032000h



Bit Range	Default & Access	Description
31:24	0Ch RO	**Base Class Code (BCC_0):** A value of 0Ch indicates that this is a Serial Bus controller.
23:16	03h RO	**Sub Class Code (SCC_0):** A value of 03h indicates that this is a Universal Serial Bus Host Controller.
15:8	20h RO	**Programming Interface (PI_0):** A value of 20h indicates that this USB2 Host Controller conforms to the EHCI specification.
7:0	00h RO	**Revision ID (RID_0):** The value reported in this register indicates stepping of the host controller hardware.

3.16.4 Reserved and Master Latency Timer and Header Type (RSVD_MLT_HT)—Offset Ch

Reserved, for padding Master Latency Timer Header Type Reserved

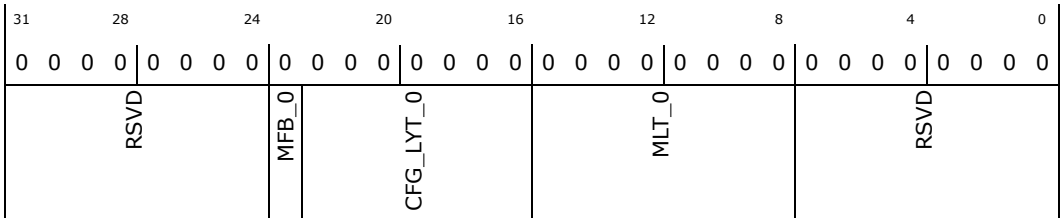
Access Method

Type: PCI Configuration Register (Size: 32 bits)

RSVD_MLT_HT: [B:0, D:29, F:0] + Ch

Power Well: Core

Default: 00000000h



Bit Range	Default & Access	Description
31:24	00h RO	**Reserved (RSVD):** Reserved.
23	0b RO	**Multi Function Bit (MFB_0):** When set to 1 this indicates that this is a multifunction device. Default to 0 since EHCI is at function 0, no other function beyond.
22:16	0000000b RO	**Configuration Layout (CFG_LYT_0):** Hardwired to 0 to indicate a standard PCI configuration layout.
15:8	00h RO	**Master Latency Timer (MLT_0):** Because the USB2 controller is internally implemented with arbitration on an internal interface, it does not need a master latency timer. The bits will be fixed at 0
7:0	00h RO	**Reserved (RSVD):** Reserved.

3.16.5 Memory Base Address (MBAR)—Offset 10h

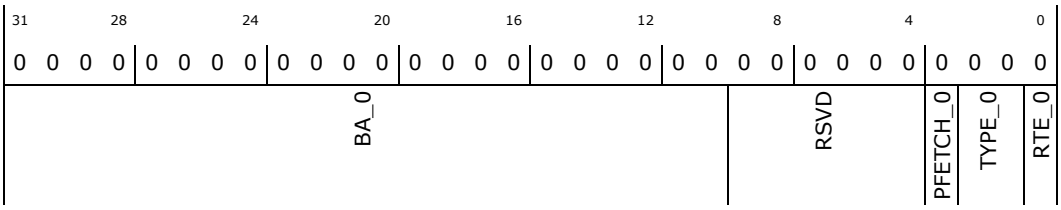
Access Method

Type: PCI Configuration Register (Size: 32 bits)

MBAR: [B:0, D:29, F:0] + 10h

Power Well: Core

Default: 00000000h



Bit Range	Default & Access	Description
31:10	000000h RW	**Base Address (BA_0):** Bits (31:10) correspond to memory address signals (31:10), respectively. This gives 1 KB of relocatable memory space aligned to 1 KB boundaries.
9:4	000000b RO	**Reserved (RSVD):** Reserved.
3	0b RO	**Prefetchable (PFETCH_0):** Read Only. This bit is hardwired to 0 indicating that this range should not be prefetched.
2:1	00b RO	**Type (TYPE_0):** indicating that this range can be mapped anywhere within 32-bit address space.
0	0b RO	**Resource Type Indicator (RTE_0):** Read Only. This bit is hardwired to 0 indicating that the base address field in this register maps to memory space

3.16.6 USB2 Subsystem Vendor ID and USB2 Subsystem ID (SSVID_SSID)—Offset 2Ch

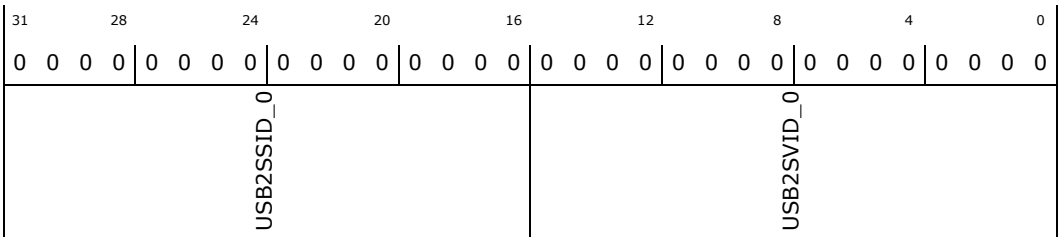
Access Method

Type: PCI Configuration Register (Size: 32 bits)

SSVID_SSID: [B:0, D:29, F:0] + 2Ch

Power Well: Core

Default: 00000000h



Bit Range	Default & Access	Description
31:16	0000h RW/L	**USB2 Subsystem ID (USB2SSID_0):** BIOS sets the value in this register to identify the Subsystem ID. This register, in combination with the Subsystem Vendor ID register, enables the operating system to distinguish each subsystem from other(s). Writes to this register are enabled when the WRT_RDONLY bit (offset 80h, bit 0) is set to 1. Writes should be done as a single 16-bit cycle. Reset: none
15:0	0000h RW/L	**USB2 Subsystem Vendor ID (USB2SVID_0):** This register, in combination with the USB2 Subsystem ID register, enables the operating system to distinguish each subsystem from the others. Writes to this register are enabled when the WRT_RDONLY bit (offset 80h, bit 0) is set to 1. Reset: none

3.16.7 Capabilities Pointer and Reserved (CAP_PTR_RSVD)—Offset 34h

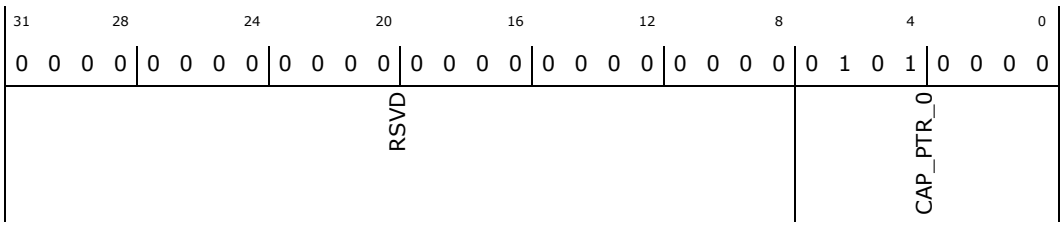
Access Method

Type: PCI Configuration Register (Size: 32 bits)

CAP_PTR_RSVD: [B:0, D:29, F:0] + 34h

Power Well: Core

Default: 00000050h



Bit Range	Default & Access	Description
31:8	000000h RO	**Reserved (RSVD):** Reserved.
7:0	50h RO	**Capabilities Pointer (CAP_PTR_0):** This register points to the starting offset of the USB2 capabilities ranges.

3.16.8 Interrupt Line and Interrupt Pin and Reserved (ILINE_IPIN_RSVD)—Offset 3Ch

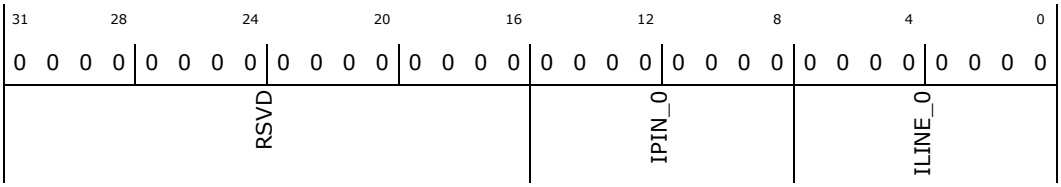
Access Method

Type: PCI Configuration Register (Size: 32 bits)

ILINE_IPIN_RSVD: [B:0, D:29, F:0] + 3Ch

Power Well: Core

Default: 00000000h



Bit Range	Default & Access	Description
31:16	0000h RO	**Reserved (RSVD):** Reserved.
15:8	00h RO	**Interrupt Pin (IPIN_0):** Bits 3:0 reflect the value programmed in the interrupt pin registers in chipset configuration space. Bits 7:4 are hardwired to 0000b. NOTE: As a single function device, only INTA# may be used while the other three interrupt lines have no meaning. (refer to PCI 3.0 spec section 2.2.6 Interrupt Pins)
7:0	00h RW	**Interrupt line (ILINE_0):** This data is not used by the SOC. It is used as a scratchpad register to communicate to software the interrupt line that the interrupt pin is connected to. Reset: core well and D3-to-D0.

3.16.9 PCI Power Management Capability ID and Next Item Pointer #1 and PM Capabilities (PM_CID_NEXT_CAP)—Offset 50h

PCI Power Management Capabilities ID Next Item Pointer #1 Power Management Capabilities

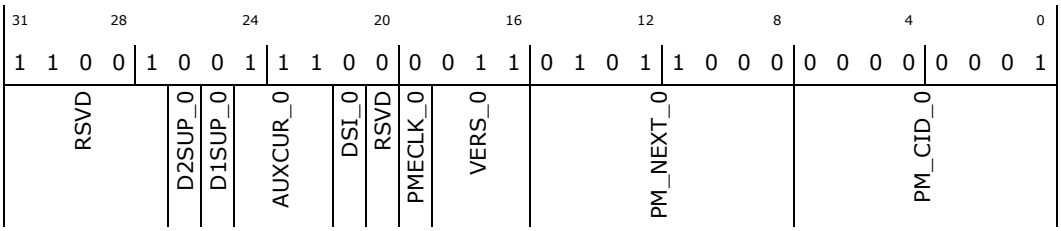
Access Method

Type: PCI Configuration Register (Size: 32 bits)

PM_CID_NEXT_CAP: [B:0, D:29, F:0] + 50h

Power Well: Core

Default: C9C35801h



Bit Range	Default & Access	Description
31:27	11001b RO	**Reserved (RSVD):** Reserved.
26	0b RO	**D2_Support (D2SUP_0):** The D2 state is not supported. Reset: core well, but not D3-to-D0.

Bit Range	Default & Access	Description
25	0b RO	**D1_Support (D1SUP_0):** The D1 state is not supported. Reset: core well, but not D3-to-D0.
24:22	111b RW/L	**Aux_Current (AUXCUR_0):** The USB2 SIP EHC reports 375mA maximum Suspend well current required when in the D3cold state. This value can be written by BIOS when a more accurate value is known.
21	0b RO	**DSI (DSI_0):** The Intel EHC reports 0, indicating that no device-specific initialization is required. Reset: core well, but not D3-to-D0.
20	0b RO	**Reserved (RSVD):** Reserved.
19	0b RO	**PME Clock (PMECLK_0):** The Intel EHC reports 0, indicating that no PCI clock is required to generate PME#. Reset: core well, but not D3-to-D0.
18:16	011b RW/L	**Version (VERS_0):** Version: The Intel EHC reports 011, indicating that it complies with Revision 1.21 of the PCI Power Management Specification. Note: As contingency plan, the bit can be reverted by BIOS to 010b to support PCI PM Revision 1.1, by manipulating the offset80h Access Control register's WRT_RDONLY bit.
15:8	58h RW/L	**Next Item Pointer #1 (PM_NEXT_0):** This register defaults to 58h, which indicates that the next capability registers begin at configuration offset 58h. This register is writable when the WRT_RDONLY bit is set. This allows BIOS to effectively hide the Debug Port capability registers, if necessary. This register should only be written during system initialization before the plug-and-play software has enabled any master-initiated traffic. Values of 58h implies Debug Port and FLR capabilities visible 98h implies Debug Port invisible, next capability is FLR 00h implies that both Debug port and FLR capability are hidden Note that this value is never expected to be programmed. Reset: core well, but not D3-to-D0
7:0	01h RO	**PCI Power Management Capability ID (PM_CID_0):** A value of 01h indicates that this is a PCI Power Management capabilities field.

3.16.10 Power Management Control/Status (PM_CS)—Offset 54h

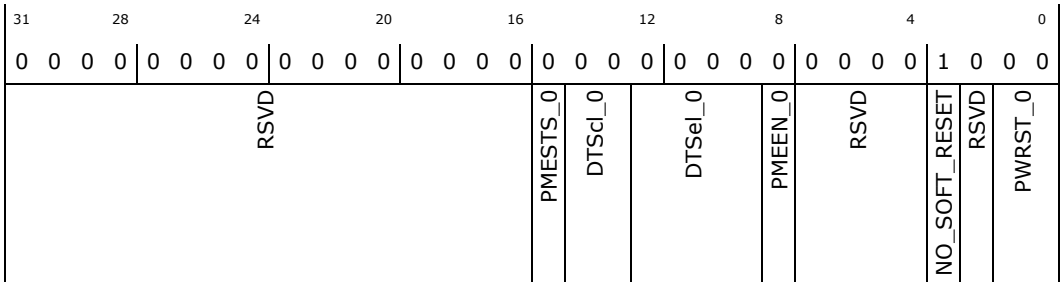
Access Method

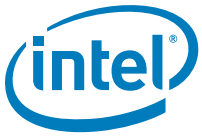
Type: PCI Configuration Register (Size: 32 bits)

PM_CS: [B:0, D:29, F:0] + 54h

Power Well: Core

Default: 00000008h





Bit Range	Default & Access	Description
31:16	0000h RO	**Reserved (RSVD):** Reserved.
15	0b RWC	**PME_Status (PMESTS_0):** This bit is set when the EHC would normally assert the PME# signal independent of the state of the PME_En bit. Writing a 1 to this bit will clear it and cause the internal PME to deassert (if enabled). Writing a 0 has no effect. This bit must be explicitly cleared by the operating system each time the operating system is loaded.
14:13	00b RO	**Data_Scale (DTScl_0):** because it does not support the associated Data register.
12:9	0h RO	**Data_Select (DTSel_0):** because it does not support the associated Data register.
8	0b RW	**PME_En (PMEEN_0):** A '1' enables the EHC to generate an internal PME signal when PME_Status is '1'. This bit must be explicitly cleared by the operating system each time it is initially loaded.
7:4	0000b RO	**Reserved (RSVD):** Reserved.
3	1b RO	**No Soft Reset (NO_SOFT_RESET):** A '0' indicates device does perform an internal reset upon D3hot to D0 transition via software control of the PowerState bits. Configuration Context is lost. Full re-initialization sequence is needed to return the device to D0 Initialized.(Default to '1') Note: As contingency plan, the bit can be reverted by BIOS to 0, by manipulating the offset80h Access Control registers WRT_RDONLY bit.
2	0b RO	**Reserved (RSVD):** Reserved.
1:0	00b RW	**PowerState (PWRST_0):** This 2-bit field is used both to determine the current power state of EHC function and to set a new power state. The definition of the field values are: 00b - D0 state 11b - D3hot state If software attempts to write a value of 10b or 01b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3hot state, the accesses to the EHC memory range must not be accepted; but the configuration space must still be accessible. When not in the D0 state, the generation of the interrupt output is blocked. Specifically, the PIRQ[H] is not asserted when not in the D0 state. When software changes this value from the D3hot state to the D0 state, an internal warm (soft) reset is generated, and software must re-initialize the function.

3.16.11 Debug Port Capability ID and Next Item Pointer #2 and Debug Port Base Offset (DP_CID_NEXT_BASE)—Offset 58h

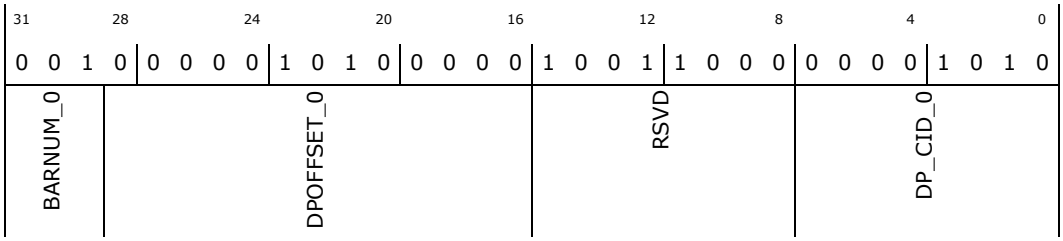
Access Method

Type: PCI Configuration Register (Size: 32 bits)

DP_CID_NEXT_BASE: [B:0, D:29, F:0] + 58h

Power Well: Core

Default: 20A0980Ah



Bit Range	Default & Access	Description
31:29	001b RO	**BAR Number (BARNUM_0):** Read-Only. This field is hardwired to 001b to indicate the memory BAR at offset 10h in the EHCI configuration space. Reset: Not applicable.
28:16	00A0h RO	**Debug Port Offset (DPOFFSET_0):** This field is hardwired to 0A0h to indicate that the debug port registers begin at offset A0h in the EHCI memory range. Reset: Not applicable.
15:8	98h RO	**Reserved (RSVD):** Reserved.
7:0	0Ah RO	**Debug Port Capability ID (DP_CID_0):** This register is hardwired to 0Ah which indicates that this is the start of a Debug Port Capability structure. Reset: Not applicable.

3.16.12 Serial Bus Release Number and Frame Length Adjustment and Port Wake Capability (SBRN_FLA_PWC)—Offset 60h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

Power Well: Resume

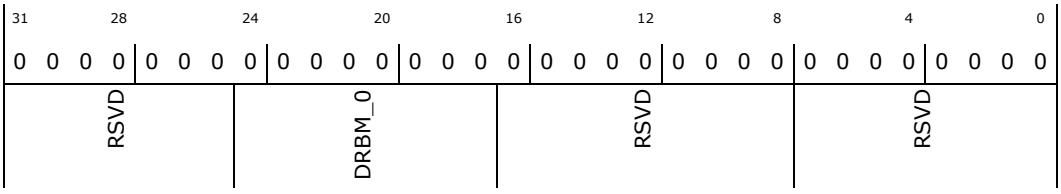
Default: 00000000h



Bit Range	Default & Access	Description
31:22	0h RWC	**SMI on PortOwner (SMIonPO1_0):** Bits 29:22 correspond to the Port Owner bits for ports 1 (22) through 8 (29). These bits are set to '1' whenever the associated Port Owner bits transition from 0-)1 or 1-)0. Software clears these bits by writing a one. This register is implemented in the Suspend Well. This register is only reset by the resume power well going low. It is not reset by the core power well going low or by a D3-to-D0 state transition
21	0b RWC	**SMI on PMCSR (SMIonPMCSR_0):** This bit is set to '1' whenever software modifies the Power State bits in the Power Management Control/Status register. This register is implemented in the Suspend Well. This register is only reset by the resume power well going low. It is not reset by the core power well going low or by a D3-to-D0 state transition
20	0b RWC	**SMI on Async (SMIonAsync_0):** This bit is set to '1' whenever the Async Schedule Enable bit transitions from 1-)0 or 0-)1. This register is implemented in the Suspend Well. This register is only reset by the resume power well going low. It is not reset by the core power well going low or by a D3-to-D0 state transition
19	0b RWC	**SMI on Periodic (SMIonPeriodic_0):** This bit is set to '1' whenever the Periodic Schedule Enable bit transitions from 1-)0 or 0-)1. This register is implemented in the Suspend Well. This register is only reset by the resume power well going low. It is not reset by the core power well going low or by a D3-to-D0 state transition
18	0b RWC	**SMI on CF (SMIonCF_0):** This bit is set to '1' whenever the Configure Flag transitions from 1-)0 or 0-)1. This register is implemented in the Suspend Well. This register is only reset by the resume power well going low. It is not reset by the core power well going low or by a D3-to-D0 state transition
17	0b RWC	**SMI on HCHalted (SMIonHCHalted_0):** This bit is set to '1' whenever HCHalted transitions to '1' as a result of the Run/Stop bit being cleared. This register is only reset by the resume power well going low. It is not reset by the core power well going low or by a D3-to-D0 state transition
16	0b RWC	**SMI on HCReset (SMIonHCRst_0):** This bit is set to '1' whenever HCRESET transitions to '1'. This register is implemented in the Suspend Well. This register is only reset by the resume power well going low. It is not reset by the core power well going low or by a D3-to-D0 state transition

15:6	000h RW	**SMI on PortOwner Enable (SMIonPOEn_0):** When any of these bits are '1' and the corresponding SMI on PortOwner bits are '1', then the host controller will issue an SMI. Unused ports should have their corresponding bits cleared. This register is only reset by the resume power well going low. It is not reset by the core power well going low or by a D3-to-D0 state transition
5	0b RW	**SMI on PMSCR Enable (SMIonPMSCREn_0):** When this bit is '1' and SMI on PMSCR is '1', then the host controller will issue an SMI. This register is only reset by the resume power well going low. It is not reset by the core power well going low or by a D3-to-D0 state transition
4	0b RW	**SMI on Async Enable (SMIonAsyncEn_0):** When this bit is '1 and SMI on Async is '1' , then the host controller will issue an SMI. This register is implemented in the Suspend Well. This register is only reset by the resume power well going low. It is not reset by the core power well going low or by a D3-to-D0 state transition
3	0b RW	**SMI on Periodic Enable (SMIonPeriodicEn_0):** When this bit is '1 and SMI on Periodic is '1', then the host controller will issue an SMI. This register is implemented in the Suspend Well. This register is only reset by the resume power well going low. It is not reset by the core power well going low or by a D3-to-D0 state transition
2	0b RW	**SMI on CF Enable (SMIonCFEn_0):** When this bit is '1' and SMI on CF is '1', then the host controller will issue an SMI. This register is implemented in the Suspend Well. This register is only reset by the resume power well going low. It is not reset by the core power well going low or by a D3-to-D0 state transition
1	0b RW	**SMI on HCHalted Enable (SMIonHCHaltedEn_0):** When this bit is a '1' and SMI on HCHalted is '1', then the host controller will issue an SMI. This register is implemented in the Suspend Well. This register is only reset by the resume power well going low. It is not reset by the core power well going low or by a D3-to-D0 state transition
0	0b RW	**SMI on HCReset Enable (SMIonHCRstEn_0):** When this bit is a '1' and SMI on HCHalted is '1', then the host controller will issue an SMI. This register is implemented in the Suspend Well. This register is only reset by the resume power well going low. It is not reset by the core power well going low or by a D3-to-D0 state transition

3.16.17 OverCurrent Mapping (OCMAP)—Offset 74h

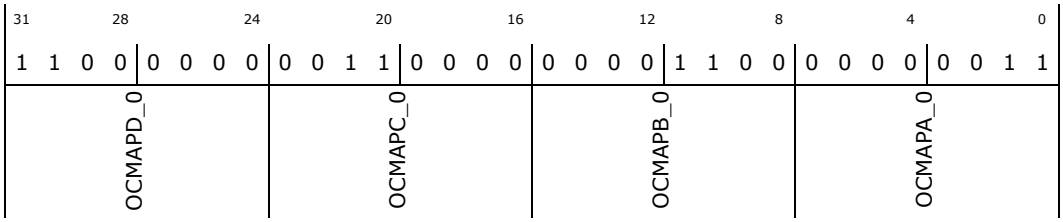
Access Method

Type: PCI Configuration Register (Size: 32 bits)

OCMAP: [B:0, D:29, F:0] + 74h

Power Well: Resume

Default: C0300C03h



Bit Range	Default & Access	Description
31:24	C0h RW	**OC Mapping D (OCMAPD_0):** Each bit position maps OC4, for EHCI1 to a set of ports as follows: The OC4 pin is ganged to the overcurrent signal of each port that has its corresponding bit set. It is SW's responsibility to ensure that a given port's bit map is set only for one OC pin.
23:16	30h RW	**OC Mapping C (OCMAPC_0):** OC Mapping C. Each bit position maps OC3, for EHCI1 to a set of ports as follows: The OC3 pin is ganged to the overcurrent signal of each port that has its corresponding bit set. It is SW's responsibility to ensure that a given port's bit map is set only for one OC pin.
15:8	0Ch RW	**OC Mapping B (OCMAPB_0):** OC Mapping B. Each bit position maps OC2, for EHCI1 to a set of ports as follows: The OC2 pin is ganged to the overcurrent signal of each port that has its corresponding bit set. It is SW's responsibility to ensure that a given port's bit map is set only for one OC pin.
7:0	03h RW	**OC Mapping A (OCMAPA_0):** OC Mapping A: Each bit position maps OC1, for EHCI1 to a set of ports as follows: The OC1 pin is ganged to the overcurrent signal of each port that has its corresponding bit set. It is SW's responsibility to ensure that a given port's bit map is set only for one OC pin.

3.16.18 EHC Suspend Well Configuration and RMH Wake Control (EHCSUSCFGRMHWC)—Offset 7Ch

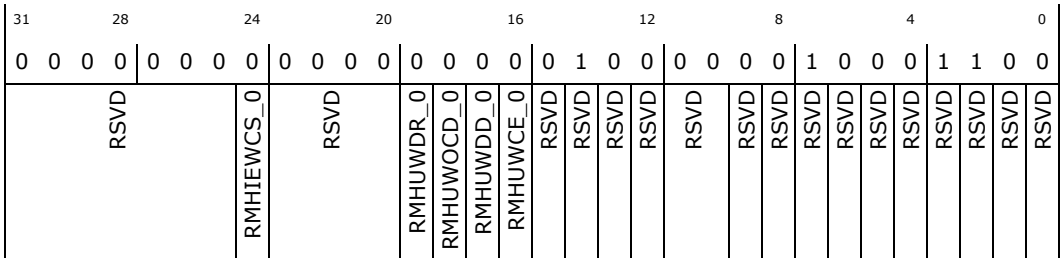
Access Method

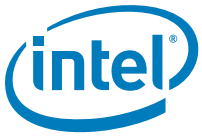
Type: PCI Configuration Register (Size: 32 bits)

EHCSUSCFGRMHWC: [B:0, D:29, F:0] + 7Ch

Power Well: Resume

Default: 0000408Ch





Bit Range	Default & Access	Description
31:25	0000000b RO	**Reserved (RSVD):** Reserved.
24	0b RW	**RMH Inherit EHCI Wake Control Settings (RMHIEWCS_0):** When this bit is set, the RMH behaves as if bits 2:0 of this register reflect the appropriate bits of EHCI PORTSC0 bits 22:20.
23:20	0000b RO	**Reserved (RSVD):** Reserved.
19	0b RW	**RMH Upstream Wake on Device Resume (RMHUWDR_0):** This bit governs the hub behavior when globally suspended. When this bit is 0 it enables the port to be sensitive to device initiated resume events as system wake-up events. i.e, the hub will initiate a resume on its upstream port and cause a wake when a device resume occurs on an enabled DS port When this bit is set to 1 and a device resume event is seen on a downstream port, the hub does not initiate a wake upstream and does not cause a wake.
18	0b RW	**RMH Upstream Wake on OC Disable (RMHUWOCD_0):** This bit governs the hub behavior when globally suspended. When this bit is 0 it enables the port to be sensitive to overcurrent conditions as system wake-up events. i.e,, the hub will initiate a resume on its upstream port and cause a wake when an OC condition occurs on an enabled DS port When this bit is set to 1 and an over current event is seen, the hub does not initiate a wake upstream and does not cause a wake.
17	0b RW	**RMH Upstream Wake on Disconnect Disable (RMHUWDD_0):** This bit governs the hub behavior when globally suspended. When this bit is set to 0, the globally suspended hub treats disconnect events on downstream port as resume events to be propagated upstream. In this case, it is allowed to initiate a wake on its upstream por and cause a system wake in response to a disconnect event on a downstream port When this bit is set to 1, and the hub is globally suspended, the hub does not initiate a resume on its upstream port or cause a resume when a disconnect event occurs on a downstream port.
16	0b RW	**RMH Upstream Wake on Connect Enable (RMHUWCE_0):** This bit governs the hub behavior when globally suspended. When this bit is set to 0, and the hub is globally suspended, the hub treats connect events on a downstream port as resume events to be propagated upstream. As well as waking up the system. When this bit is set to 1,and the hub is globally suspended, the hub does not wake the system nor does it initiate a resume on its upstream port when a connect event occurs on a downstream port.

3.17.1 Capability Registers Length and HC Interface Version Number (CAP_HCIV)—Offset 0h

Access Method

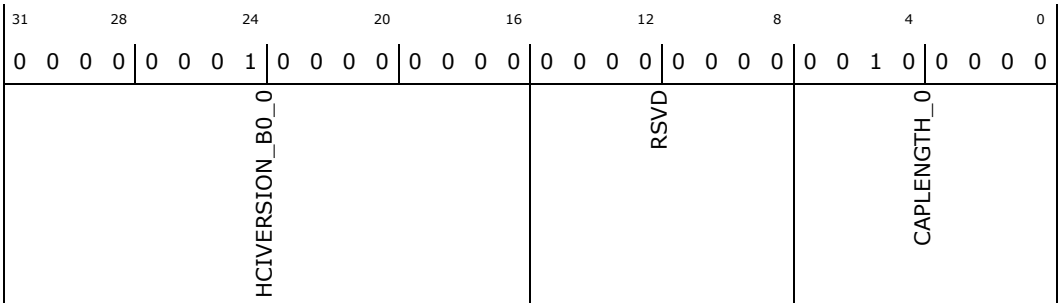
Type: Memory Mapped I/O Register (Size: 32 bits)

CAP_HCIV: [MBAR] + 0h

MBAR Type: PCI Configuration Register (Size: 32 bits)
MBAR Reference: [B:0, D:29, F:0] + 10h

Power Well: Core

Default: 01000020h



Bit Range	Default & Access	Description
31:16	0100h RO	**Host Controller Interface Version Number (HCIVERSION_B0_0):** This is a two-byte register containing a BCD encoding of the version number of interface that this host controller interface conforms.
15:8	00h RO	**Reserved (RSVD):** Reserved.
7:0	20h RO	**Capability Registers Length (CAPLENGTH_0):** This register is used as an offset to add to the Memory Base Register to find the beginning of the Operational Register Space. This is fixed at 20h, indicating that the Operation Registers begin at offset 20h.

3.17.2 Host Controller Structural Parameters (HCSPARAMS)—Offset 4h

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

HCSPARAMS: [MBAR] + 4h

MBAR Type: PCI Configuration Register (Size: 32 bits)
MBAR Reference: [B:0, D:29, F:0] + 10h

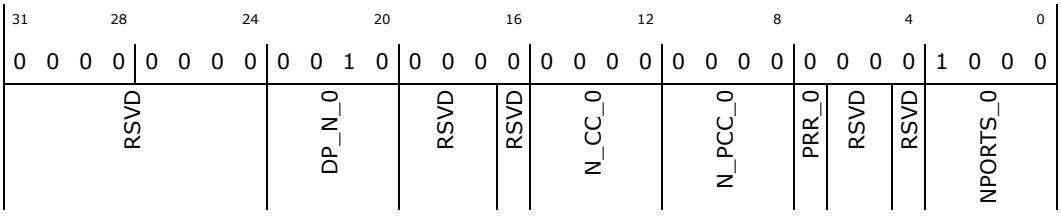
Default: 00200008h



Bit Range	Default & Access	Description
31:24	00h RO	**Reserved (RSVD):** Reserved.
23:20	2h RO	**Debug Port Number (DP_N_0):** Hardwired to 2h, indicating that the Debug Port is on the 2nd port on the EHC. This register is only reset by the resume power well going low. It is not reset by a D3-to-D0 state transition or HCRESET (Host Controller Reset)
19:17	000b RO	**Reserved (RSVD):** Reserved.
16	0b RO	**Reserved (RSVD):** Reserved.
15:12	0h RO	**Number of Companion Controllers (N_CC_0):** This field indicates the number of companion controllers associated with this USB 2.0 host controller. A zero in this field indicates there are no companion host controllers. Port-ownership hand-off is not supported. Only high-speed devices are supported on the host controller root ports. A value larger than one in this field indicates there are companion USB 1.1 host controller(s). Port-ownership hand-offs are supported. High, Full- and Low-speed devices are supported on the host controller root ports. There are no companion controllers. This field is set to '0' as Read-Only bit.
11:8	0h RO	**Number of Ports per Companion Controller (N_PCC_0):** This field indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to system software. Read-Only. This register is only reset by the resume power well going low. It is not reset by a D3-to-D0 state transition or HCRESET (Host Controller Reset)
7	0b RO	**Port Routing Rules (PRR_0):** This field indicates the method used by this implementation for how all ports are mapped to companion controllers. This is hardwired to 0, indicating that the first N_PCC (=2) ports are routed to the lowest numbered function companion host controller, the next N_PCC ports are routed to the next lowest function companion controller, and so on
6:5	00b RO	**Reserved (RSVD):** Reserved.
4	0b RO	**Reserved (RSVD):** Reserved.
3:0	8h RW	**N_PORTS (NPORTS_0):** This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register Space. Valid values are in the range of 1H to FH. The default value for the EHCI controller indicates 8 ports. BIOS may overwrite the default value to properly describe the board or chip SKU . (please refer to RMH Configuration Details in section 1.23.2). A zero in this field is undefined. Integrated RMH - If USBr is disabled, this should be updated by BIOS to 2 such that the EHC reports 2ports to be default, port 0 assigned to the RMH and port 1 assigned to the debug device. If USB-R is enabled, the number reported should be updated to 3 by BIOS (port 2 will be assigned to USB-R in this case) Legacy Mode - The default value for the EHCI controller indicates 8 ports. If USB-R support is enabled, BIOS should account for the additional ports in calculating the value to write to this field.

3.17.3 Host Controller Capability Parameters (HCCPARAMS)—Offset 8h

Access Method

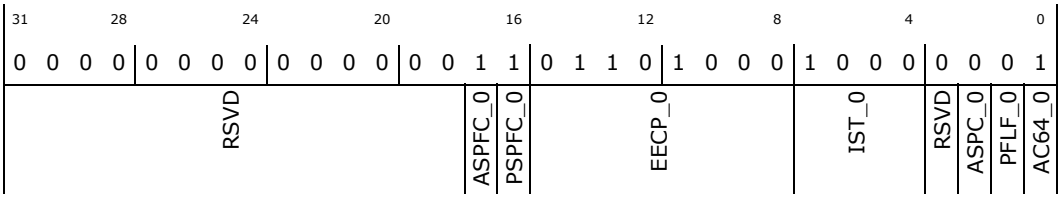
Type: Memory Mapped I/O Register (Size: 32 bits)

HCCPARAMS: [MBAR] + 8h

MBAR Type: PCI Configuration Register (Size: 32 bits)
MBAR Reference: [B:0, D:29, F:0] + 10h

Power Well: Resume

Default: 00036881h



Bit Range	Default & Access	Description
31:18	00000000000000b RO	**Reserved (RSVD):** Reserved.
17	1b RW	**Asynchronous Schedule Prefetch Capability (ASPFC_0):** This bit indicates that the hardware support the Asynch schedule prefetch enable bit in the USB command register.
16	1b RW	**Periodic Schedule Prefetch Capability (PSPFC_0):** This bit indicates that the EHC hardware supports the Periodic Schedule prefetch bit in the USB2 Command Register.
15:8	68h RO	**EHCI Extended Capabilities Pointer (EECP_0):** This field is hardwired to 68h, indicating that the EHCI capabilities list exists and begins at offset 68h in the PCI configuration space.
7:4	8h RO	**Isochronous Scheduling Threshold (IST_0):** This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame. Refer to the EHCI specification for details on how software uses this information for scheduling isochronous transfers. The Intel USB2 hardwires this field to 8h.
3	0b RO	**Reserved (RSVD):** Reserved.
2	0b RO	**Asynchronous Schedule Park Capability (ASPC_0):** This bit is hardwired to 0 indicating that the Host Controller does not support this optional feature.

Bit Range	Default & Access	Description
1	0b RO	**Programmable Frame List Flag (PFLF_0):** If this bit is set to a zero, then system software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero. If set to a one, then system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K page boundary. This requirement ensures that the frame list is always physically contiguous. The Intel EHC does not support different frame list lengths. This bit is read-only '0'.
0	1b RO	**64-bit Addressing Capability (AC64_0):** This field documents the addressing range capability of this implementation. The value of this field determines whether software should use the 32-bit or 64-bit data structures. Values for this field have the following interpretation:0b data structures using 32-bit address memory pointers; 1b data structures using 64-bit address memory pointers The USB2 SIP supports 64-bit addressing only. This bit is read-only '1'.

3.17.4 USB2 Command Register (USB2CMD)—Offset 20h

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

USB2CMD: [MBAR] + 20h

MBAR Type: PCI Configuration Register (Size: 32 bits)
MBAR Reference: [B:0, D:29, F:0] + 10h

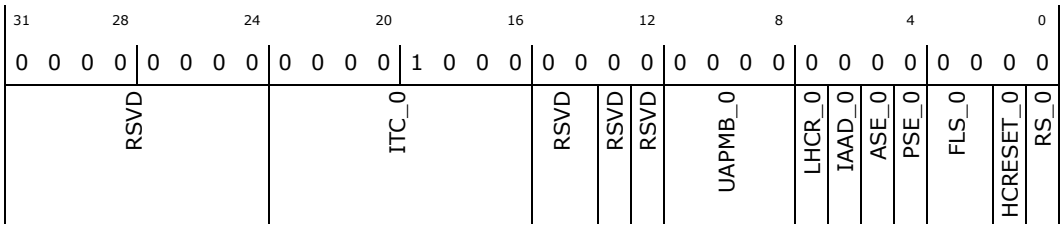
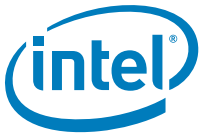
Default: 00080000h



Bit Range	Default & Access	Description
31:24	00h RO	**Reserved (RSVD):** Reserved.
23:16	08h RW	**Interrupt Threshold Control (ITC_0):** This field is used by system software to select the maximum rate at which the host controller will issue interrupts. The only valid values are defined below. If software writes an invalid value to this register, the results are undefined. Value Maximum Interrupt Interval 00h Reserved 01h 1 micro-frame 02h 2 micro-frames 04h 4 micro-frames 08h 8 micro-frames (default, equates to 1 ms) 10h 16 micro-frames (2 ms) 20h 32 micro-frames (4 ms) 40h 64 micro-frames (8 ms) Refer to Section 4 in the EHCI specification for interrupts affected by this field.



Bit Range	Default & Access	Description
15:14	00b RO	**Reserved (RSVD):** Reserved.
13	0b RO	**Reserved (RSVD):** Reserved.
12	0h RO	**Reserved (RSVD):** Reserved.
11:8	0h RO	**Unimplemented Asynchronous Park Mode Bits (UAPMB_0):** This field is hardwired to 000b because the host controller does not support this optional feature.
7	0b RO	**Light Host Controller Reset (LHCR_0):** Read Only 0b. The Intel EHC does not implement this optional reset and hardwires this bit to 0.
6	0b RW	**Interrupt on Async Advance Doorbell (IAAD_0):** This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Software must write a 1 to this bit to ring the doorbell. When the host controller has evicted all appropriate cached schedule state , it sets the Interrupt on Async Advance status bit in the USBSTS register. If the Interrupt on Async Advance Enable bit in the USBINTR register is a one then the host controller will assert an interrupt at the next interrupt threshold. See the EHCI specification for operational details. The host controller sets this bit to a zero after it has set the Interrupt on Async Advance status bit in the USBSTS register to a one. Software should not write a one to this bit when the asynchronous schedule is disabled. Doing so will yield undefined results.
5	0b RW	**Asynchronous Schedule Enable (ASE_0):** This bit controls whether the host controller skips processing the Asynchronous Schedule. Values mean: 0b Do not process the Asynchronous Schedule 1b Use the ASYNCLISTADDR register to access the Asynchronous Schedule.
4	0b RW	**Periodic Schedule Enable (PSE_0):** This bit controls whether the host controller skips processing the Periodic Schedule. Values mean: 0b Do not process the Periodic Schedule 1b Use the PERIODICLISTBASE register to access the Periodic Schedule.
3:2	00b RO	**Frame List Size (FLS_0):** This field is R/W only if Programmable Frame List Flag in the HCCPARAMS registers is set to a one. . This field specifies the size of the frame list. The size the frame list controls which bits in the Frame Index Register should be used for the Frame List Current index. Values mean:00b 1024 elements (4096 bytes) Default value; 01b 512 elements (2048 bytes); 10b 256 elements (1024 bytes) - for resource-constrained environments

Bit Range	Default & Access	Description
1	0b RW	**Host Controller Reset (HCRESET_0):** This control bit used by software to reset the host controller. The effects of this on Root Hub registers are similar to a Chip Hardware Reset. When software writes a one to this bit, the Host Controller resets its internal pipelines, timers, counters, state machines, etc. to their initial value. Any transaction currently in progress on USB is immediately terminated. A USB reset is not driven on downstream ports. Note: PCI Configuration registers and Host Controller Capability Registers are not affected by this reset. All operational registers, including port registers and port state machines are set to their initial values. Port ownership will be disowned by the host controller(s), with the side effects described in the EHCI spec. Software must re initialize the host controller in order to return the host controller to an operational state. This bit is set to zero by the Host Controller when the reset process is complete. Software cannot terminate the reset process early by writing a zero to this register. Software should not set this bit to a one when the HCHalted bit in the USBSTS register is a zero. Attempting to reset an actively running host controller will result in undefined behavior. This reset must be used to leave EHCI port test modes.
0	0b RW	**Run/Stop (RS_0):** 1=Run. 0=Stop. When set to a 1, the Host Controller proceeds with execution of the schedule. The Host Controller continues execution as long as this bit is set to a 1. When this bit is set to 0, the Host Controller completes the current and any actively pipelined transactions on the USB and then halts. The Host Controller must halt within 16 microframes after software clears the Run bit. The HC Halted bit in the status register indicates when the Host Controller has finished its pending pipelined transactions and has entered the stopped state. Software should not write a 1 to this field unless the host controller is in the Halted state (i.e. HCHalted in the USBSTS register is a one). The following table explains how the different combinations of Run and Halted must be interpreted: Run/Stop Halted Interpretation 0 0 Valid- in the process of halting 0 1 Valid- halted 1 0 Valid- running 1 1 Invalid- the HCHalted bit clears immediately Memory read cycles initiated by the EHC that receive any status other than Successful will result in this bit being cleared (and also affect the Host Error bit).

3.17.5 USB2 Status (USB2STS)—Offset 24h

Access Method

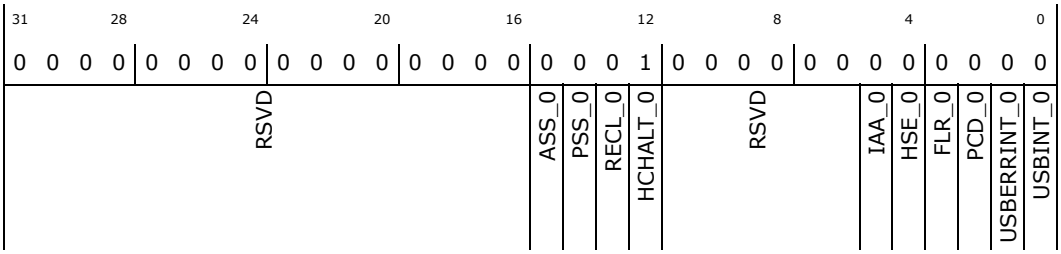
Type: Memory Mapped I/O Register (Size: 32 bits)

USB2STS: [MBAR] + 24h

MBAR Type: PCI Configuration Register (Size: 32 bits)
MBAR Reference: [B:0, D:29, F:0] + 10h

Power Well: Core

Default: 00001000h



Bit Range	Default & Access	Description
31:16	0000h RO	**Reserved (RSVD):** Reserved.
15	0b RO	**Asynchronous Schedule Status (ASS_0):** This bit reports the current real status of the Asynchronous Schedule. If this bit is a zero then the status of the Asynchronous Schedule is disabled. If this bit is a one then the status of the Asynchronous Schedule is enabled. The Host Controller is not required to immediately disable or enable the Asynchronous Schedule when software transitions the Asynchronous Schedule Enable bit in the USBCMD register. When this bit and the Asynchronous Schedule Enable bit are the same value, the Asynchronous Schedule is either enabled (1) or disabled (0).
14	0b RO	**Periodic Schedule Status (PSS_0):** This bit reports the current real status of the Periodic Schedule. If this bit is a zero then the status of the Periodic Schedule is disabled. If this bit is a one then the status of the Periodic Schedule is enabled. The Host Controller is not required to immediately disable or enable the Periodic Schedule when software transitions the Periodic Schedule Enable bit in the USBCMD register. When this bit and the Periodic Schedule Enable bit are the same value, the Periodic Schedule is either enabled (1) or disabled (0). The Prefetch-Based Pause feature prevents this bit from transitioning to 0 if it currently has a request pending, in addition to the regular Periodic DMA engine.
13	0b RO	**Reclamation (RECL_0):** This is a read-only status bit, which is used to detect an empty asynchronous schedule. The operational model and valid transitions for this bit are described in Section 4 of the EHCI Specification.
12	1b RO	**HCHalted (HCHALT_0):** This bit is a zero whenever the Run/Stop bit is a one. The Host Controller sets this bit to 1 after it has stopped executing as a result of the Run/Stop bit being set to 0, either by software or by the Host Controller hardware (e.g. internal error). The Prefetch-Based Pause feature prevents this bit from transitioning to 0 if it is currently has a request pending, in addition to the regular DMA engines.
11:6	000000b RO	**Reserved (RSVD):** Reserved.
5	0b RWC	**Interrupt on Async Advance (IAA_0):** System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the USBCMD register. This status bit indicates the assertion of that interrupt source.

Bit Range	Default & Access	Description
4	0b RWC	**Host System Error (HSE_0):** The Host Controller sets this bit to 1 when a serious error occurs during a host system access involving the Host Controller module. Memory read cycles initiated by the EHC that receive any status other than Successful will result in this bit being set. When this error occurs, the Host Controller clears the Run/Stop bit in the Command register to prevent further execution of the scheduled TDs. A hardware interrupt is generated to the system (if enabled in the Interrupt Enable Register).
3	0b RWC	**Frame List Rollover (FLR_0):** The Host Controller sets this bit to a one when the Frame List Index (see Section 9.3.2.4) rolls over from its maximum value to zero. Since the USB2 SIP only supports the 1024-entry Frame List Size, the Frame List Index rolls over every time FRNUM[13] toggles.
2	0b RWC	**Port Change Detect (PCD_0):** The Host Controller sets this bit to a one when any port for which the Port Owner bit is set to zero has a change bit transition from a zero to a one or a Force Port Resume bit transition from a zero to a one as a result of a J-K transition detected on a suspended port. This bit will also be set as a result of the Connect Status Change being set to a one after system software has relinquished ownership of a connected port by writing a zero to a port's Port Owner bit. This bit is allowed to be maintained in the Auxiliary power well. Alternatively, it is also acceptable that on a D3 to D0 transition of the EHCI HC device, this bit is loaded with the OR of all of the PORTSC change bits (including: Force port resume, over-current change, enable/disable change and connect status change). Regardless of the implementation, whenever this bit is readable (i.e., in the D0 state), it must provide a valid view of the Port Status registers.
1	0b RWC	**USB Error Interrupt (USBERRINT_0):** The Host Controller sets this bit to 1 when completion of a USB transaction results in an error condition (e.g., error counter underflow). If the TD on which the error interrupt occurred also had its IOC bit set, both this bit and Bit 0 are set. See the EHCI specification for a list of the USB errors that will result in this interrupt being asserted.
0	0b RWC	**USB Interrupt (USBINT_0):** The Host Controller sets this bit to 1 on the completion of a USB transaction, which results in the retirement of a Transfer Descriptor that had its IOC bit set. The Host Controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes).

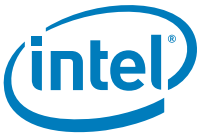
31:23	000h RO	**Reserved (RSVD):** Reserved.
22	0b RW	**Wake on Over-current Enable (WKOCE_P0_0):** Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Over-current Active bit (bit 4 of this register) is set.
21	0b RW	**Wake on Disconnect Enable (WKDSCNNTE_P0_0):** Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Current Connect Status changes from connected to disconnected (i.e., bit 0 of this register changes from 1 to 0).
20	0b RW	**Wake on Connect Enable (WKCNNTE_P0_0):** Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Current Connect Status changes from disconnected to connected (i.e., bit 0 of this register changes from 0 to 1).
19:16	0h RW	**Port Test Control (PTC_P0_0):** When this field is zero, the port is NOT operating in a test mode. A non-zero value indicates that it is operating in test mode and the specific test mode is indicated by the specific value. The encoding of the test mode bits are (0110b - 1111b are reserved): Bits Test Mode 0000b Test mode not enabled 0001b Test J_STATE- During this test mode the hardware forces pre-emphasis disabled to the AFE if bit 29 of the USB2 Safe Mode Register is set (config offset FCh.bit 29) 0010b Test K_STATE- During this test mode the hardware forces pre-emphasis disabled to the AFE if bit 29 of the USB2 Safe Mode Register is set (config offset FCh.bit 29) 0011b Test SE0_NAK 0100b Test Packet 0101b Test FORCE_ENABLE Refer to USB Specification Revision 2.0, Chapter 7 and the EHCI specification, Chapter 4 for details on each test mode. The EHC does not support the option to run the port tests while the Run/Stop bit is a one.
15:14	00b RW	**Port Indicator Control (PIC_P0_0):** Writing to these bits directly controls the corresponding LED output pins. Bit 15 is inverted to generate USBLEDG#(n) where n is the port number. Bit 14 is inverted to generate USBLEDA#(n). Software is responsible for controlling these as specified in the USB Specification Revision 2.0. Bit Value Meaning 00b Port indicators are off 01b Amber 10b Green 11b Undefined The Intel EHC only supports bit value of 00b. Other values will result in unspecified behavior.
13	1b RW	**Port Owner (PO_P0_0):** This bit unconditionally goes to a 0b when the Configure Flag makes a 0b to 1b transition. This bit unconditionally goes to 1b whenever the Configure Flag bit is zero. System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that a companion host controller owns and controls the port. See Section 4 of the EHCI Specification for operational details.
12	1b RO	**Port Power (PP_P0_0):** Hard-wired with a value of '1' on the Intel EHC. This indicates that the port does have power.



Bit Range	Default & Access	Description
11:10	00b RO	**Line Status (LS_P0_0):** These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. These bits are used for detection of low-speed USB devices prior to the port reset and enable sequence. This field is valid only when the port enable bit is zero and the current connect status bit is set to a one. The encoding of the bits are: Bits(11:10) USB State Interpretation 00b SE0 Not Low-speed device, perform EHCI reset 10b J-state Not Low-speed device, perform EHCI reset 01b K-state Low-speed device, release ownership of port 11b Undefined Not Low-speed device, perform EHCI reset
9	0b RO	**Reserved (RSVD):** Reserved.
8	0b RW	**Port Reset (PORTRST_P0_0):** 1=Port is in Reset. 0=Port is not in Reset. Default = 0. When software writes a one to this bit (from a zero), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the USB Specification Revision 2.0, completes. Note: when software writes this bit to a one, it must also write a zero to the Port Enable bit. Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detets that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared.
7	0b RW	**Suspend (SUSP_P0_0):** 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when:Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined.

Bit Range	Default & Access	Description
6	0b RW	**Force Port Resume (FPR_P0_0):** 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero.
5	0b RWC	**Over-current Change (OCC_P0_0):** This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner.
4	0b RO	**Over-current Active (OCACT_P0_0):** 1=This port currently has an over-current condition. 0=This port does not have an over-current condition. This bit will automatically transition from a one to a zero when the over current condition is removed. The functionality of this bit is not dependent upon the port owner. The Intel EHC automatically disables the port when the over-current active bit is '1'.
3	0b RWC	**Port Enable/Disable Change (PEDC_P0_0):** 1=Port enabled/disabled status has changed. 0=No change. For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it.
2	0b RO	**Reserved (RSVD):** Reserved.
1	0b RWC	**Connect Status Change (CSC_P0_0):** 1=Change in Current Connect Status. 0=No change. Indicates a change has occurred in the port's Current Connect Status. The host controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software sets this bit to 0 by writing a 1 to it.
0	0b RO	**Current Connect Status (CCS_P0_0):** 1=Device is present on port. 0=No device is present. This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set.

Bit Range	Default & Access	Description
31:23	000h RO	**Reserved (RSVD):** Reserved.
22	0b RW	**Wake on Over-current Enable (WKOCE_P0_0):** Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Over-current Active bit (bit 4 of this register) is set.
21	0b RW	**Wake on Disconnect Enable (WKDSCNNTE_P0_0):** Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Current Connect Status changes from connected to disconnected (i.e., bit 0 of this register changes from 1 to 0).
20	0b RW	**Wake on Connect Enable (WKCNNTE_P0_0):** Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. When enabled to do so, the EHC sets the PME Status bit in the Power Management Control/Status Register (offset 54, bit 15) when the Current Connect Status changes from disconnected to connected (i.e., bit 0 of this register changes from 0 to 1).

Bit Range	Default & Access	Description
19:16	0h RW	**Port Test Control (PTC_P0_0):** When this field is zero, the port is NOT operating in a test mode. A non-zero value indicates that it is operating in test mode and the specific test mode is indicated by the specific value. The encoding of the test mode bits are (0110b - 1111b are reserved): Bits Test Mode 0000b Test mode not enabled 0001b Test J_STATE- During this test mode the hardware forces pre-emphasis disabled to the AFE if bit 29 of the USB2 Safe Mode Register is set (config offset FCh.bit 29) 0010b Test K_STATE- During this test mode the hardware forces pre-emphasis disabled to the AFE if bit 29 of the USB2 Safe Mode Register is set (config offset FCh.bit 29) 0011b Test SE0_NAK 0100b Test Packet 0101b Test FORCE_ENABLE Refer to USB Specification Revision 2.0, Chapter 7 and the EHCI specification, Chapter 4 for details on each test mode. The EHC does not support the option to run the port tests while the Run/Stop bit is a one.
15:14	00b RW	**Port Indicator Control (PIC_P0_0):** Writing to these bits directly controls the corresponding LED output pins. Bit 15 is inverted to generate USBLEDG#(n) where n is the port number. Bit 14 is inverted to generate USBLEDA#(n). Software is responsible for controlling these as specified in the USB Specification Revision 2.0. Bit Value Meaning 00b Port indicators are off 01b Amber 10b Green 11b Undefined The Intel EHC only supports bit value of 00b. Other values will result in unspecified behavior.
13	1b RW	**Port Owner (PO_P0_0):** This bit unconditionally goes to a 0b when the Configure Flag makes a 0b to 1b transition. This bit unconditionally goes to 1b whenever the Configure Flag bit is zero. System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that a companion host controller owns and controls the port. See Section 4 of the EHCI Specification for operational details.
12	1b RO	**Port Power (PP_P0_0):** Hard-wired with a value of '1' on the Intel EHC. This indicates that the port does have power.
11:10	00b RO	**Line Status (LS_P0_0):** These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. These bits are used for detection of low-speed USB devices prior to the port reset and enable sequence. This field is valid only when the port enable bit is zero and the current connect status bit is set to a one. The encoding of the bits are: Bits(11:10) USB State Interpretation 00b SE0 Not Low-speed device, perform EHCI reset 10b J-state Not Low-speed device, perform EHCI reset 01b K-state Low-speed device, release ownership of port 11b Undefined Not Low-speed device, perform EHCI reset
9	0b RO	**Reserved (RSVD):** Reserved.

Bit Range	Default & Access	Description
8	0b RW	**Port Reset (PORTRST_P0_0):** 1=Port is in Reset. 0=Port is not in Reset. Default = 0. When software writes a one to this bit (from a zero), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the USB Specification Revision 2.0, completes. Note: when software writes this bit to a one, it must also write a zero to the Port Enable bit. Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detets that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared.
7	0b RW	**Suspend (SUSP_P0_0):** 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when:Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined.

Bit Range	Default & Access	Description
6	0b RW	**Force Port Resume (FPR_P0_0):** 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero.
5	0b RWC	**Over-current Change (OCC_P0_0):** This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner.
4	0b RO	**Over-current Active (OCACT_P0_0):** 1=This port currently has an over-current condition. 0=This port does not have an over-current condition. This bit will automatically transition from a one to a zero when the over current condition is removed. The functionality of this bit is not dependent upon the port owner. The Intel EHC automatically disables the port when the over-current active bit is '1'.
3	0b RWC	**Port Enable/Disable Change (PEDC_P0_0):** 1=Port enabled/disabled status has changed. 0=No change. For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it.
2	0b RO	**Reserved (RSVD):** Reserved.
1	0b RWC	**Connect Status Change (CSC_P0_0):** 1=Change in Current Connect Status. 0=No change. Indicates a change has occurred in the port's Current Connect Status. The host controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software sets this bit to 0 by writing a 1 to it.
0	0b RO	**Current Connect Status (CCS_P0_0):** 1=Device is present on port. 0=No device is present. This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set.

Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero.
5	0b RWC	**Over-current Change (OCC_P0_0):** This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner.
4	0b RO	**Over-current Active (OCACT_P0_0):** 1=This port currently has an over-current condition. 0=This port does not have an over-current condition. This bit will automatically transition from a one to a zero when the over current condition is removed. The functionality of this bit is not dependent upon the port owner. The Intel EHC automatically disables the port when the over-current active bit is '1'.
3	0b RWC	**Port Enable/Disable Change (PEDC_P0_0):** 1=Port enabled/disabled status has changed. 0=No change. For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it.
2	0b RO	**Reserved (RSVD):** Reserved.
1	0b RWC	**Connect Status Change (CSC_P0_0):** 1=Change in Current Connect Status. 0=No change. Indicates a change has occurred in the port's Current Connect Status. The host controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software sets this bit to 0 by writing a 1 to it.
0	0b RO	**Current Connect Status (CCS_P0_0):** 1=Device is present on port. 0=No device is present. This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set.

This bit unconditionally goes to 1b whenever the Configure Flag bit is zero. System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that a companion host controller owns and controls the port. See Section 4 of the EHCI Specification for operational details.

Bit Range	Default & Access	Description
8	0b RW	**Port Reset (PORTRST_P0_0):** 1=Port is in Reset. 0=Port is not in Reset. Default = 0. When software writes a one to this bit (from a zero), the bus reset sequence as defined in the USB Specification Revision 2.0 is started. Software writes a zero to this bit to terminate the bus reset sequence. Software must keep this bit at a one long enough to guarantee the reset sequence, as specified in the USB Specification Revision 2.0, completes. Note: when software writes this bit to a one, it must also write a zero to the Port Enable bit. Note that when software writes a zero to this bit there may be a delay before the bit status changes to a zero. The bit status will not read as a zero until after the reset has completed. If the port is in high-speed mode after reset is complete, the host controller will automatically enable this port (e.g. set the Port Enable bit to a one). A host controller must terminate the reset and stabilize the state of the port within 2 milliseconds of software transitioning this bit from a one to a zero. For example: if the port detets that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared.
7	0b RW	**Suspend (SUSP_P0_0):** 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when:Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined.

6	0b RW	**Force Port Resume (FPR_P0_0):** 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero.

For example: if the port detets that the attached device is high-speed during reset, then the host controller must have the port in the enabled state within 2ms of software writing this bit to a zero. The HCHalted bit in the USB2STS register should be a zero before software attempts to use this bit. The host controller may hold Port Reset asserted to a one when the HCHALTED bit is a one. The Run/Stop bit in the Command Register must be set in order for the Port Reset bit to be cleared.
7	0b RW	**Suspend (SUSP_P0_0):** 1=Port in suspend state. 0=Port not in suspend state. Port Enabled Bit and Suspend bit of this register define the port states as follows: Bits [Port Enabled, Suspend] Port State 0X Disable 10 Enable 11 Suspend When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction, if a transaction was in progress when this bit was written to a 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB. A write of zero to this bit is ignored by the host controller. The host controller will unconditionally set this bit to a zero when:Software sets the Force Port Resume bit to a zero (from a one). Software sets the Port Reset bit to a one (from a zero). If host software sets this bit to a one when the port is not enabled (i.e. Port enabled bit is a zero) the results are undefined.

Bit Range	Default & Access	Description
6	0b RW	**Force Port Resume (FPR_P0_0):** 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. This functionality defined for manipulating this bit depends on the value of the Suspend bit. For example, if the port is not suspended (Suspend and Enabled bits are a one) and software transitions this bit to a one, then the effects on the bus are undefined. Software sets this bit to a 1 to drive resume signaling. The Host Controller sets this bit to a 1 if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to a one. If software sets this bit to a one, the host controller must not set the Port Change Detect bit. Note that when the EHCI controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. Software must appropriately time the Resume and set this bit to a zero when the appropriate amount of time has elapsed. Writing a zero (from one) causes the port to return to high-speed mode (forcing the bus below the port into a high-speed idle). This bit will remain a one until the port has switched to the high-speed idle. The host controller must complete this transition within 2 milliseconds of software setting this bit to a zero.
5	0b RWC	**Over-current Change (OCC_P0_0):** This bit gets set to a one when there is a change to the Over-current Active bit. Software clears this bit by writing a one to this bit position. The functionality of this bit is not dependent upon the port owner.
4	0b RO	**Over-current Active (OCACT_P0_0):** 1=This port currently has an over-current condition. 0=This port does not have an over-current condition. This bit will automatically transition from a one to a zero when the over current condition is removed. The functionality of this bit is not dependent upon the port owner. The Intel EHC automatically disables the port when the over-current active bit is '1'.
3	0b RWC	**Port Enable/Disable Change (PEDC_P0_0):** 1=Port enabled/disabled status has changed. 0=No change. For the root hub, this bit gets set to a one only when a port is disabled due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification for the definition of a port error). This bit is not set due to the Disabled-to-Enabled transition, nor due to a disconnect. Software clears this bit by writing a 1 to it.
2	0b RO	**Reserved (RSVD):** Reserved.
1	0b RWC	**Connect Status Change (CSC_P0_0):** 1=Change in Current Connect Status. 0=No change. Indicates a change has occurred in the port's Current Connect Status. The host controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be 'setting' an already-set bit (i.e., the bit will remain set). Software sets this bit to 0 by writing a 1 to it.
0	0b RO	**Current Connect Status (CCS_P0_0):** 1=Device is present on port. 0=No device is present. This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set.

3.17.20 Debug Port Control/Status Register (DP_CTRLSTS)—Offset A0h

Access Method

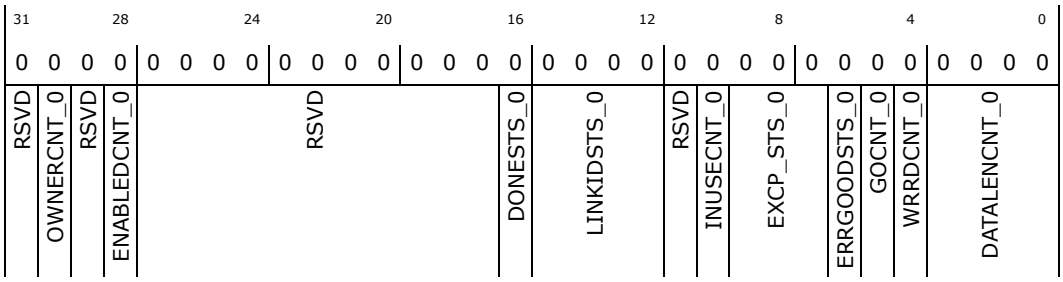
Type: Memory Mapped I/O Register (Size: 32 bits)

DP_CTRLSTS: [MBAR] + A0h

MBAR Type: PCI Configuration Register (Size: 32 bits)
MBAR Reference: [B:0, D:29, F:0] + 10h

Power Well: Core

Default: 00000000h



Bit Range	Default & Access	Description
31	0b RO	**Reserved (RSVD):** Reserved.
30	0b RW	**OWNER_CNT (OWNERCNT_0):** When software writes a 1 to this bit, the ownership of the debug port is forced to the EHCI controller (i.e. immediately taken away from the companion Classic USB Host Controller) If the port was already owned by the EHCI controller, then setting this bit has no effect. This bit overrides all of the ownership-related bits in the standard EHCI registers. Note that the value in this bit does not affect the value reported in the PORTSC Port Owner bit.
29	0b RO	**Reserved (RSVD):** Reserved.
28	0b RW	**ENABLED_CNT (ENABLEDCNT_0):** This bit = 1 if the debug port is enabled for operation. Software can clear this by writing a zero to it. The hardware clears the bit for the same conditions where hardware clears the Port Enable/Disable bit (in the PORTSC register). (Note this bit is not cleared when software clears the Port Enabled/Disabled bit in the PORTSC.) Software can directly set this bit if the port is already enabled in the associated Port Status and Control register (this is enforced by the hardware). Reset default = 0.
27:17	00000000000b RO	**Reserved (RSVD):** Reserved.
16	0b RWC	**DONE_STS (DONESTS_0):** Read/Write-Clear. This bit is set by hardware to indicate that the request is complete. Writing a 1 to this bit will clear it if it is set. Writing a 0 to this bit has no effect. Reset default = 0
15:12	0000b RO	**LINK_ID_STS (LINKIDSTS_0):** Read-Only. This field identifies the link interface. It is hardwired to 0h to indicate that it is a USB Debug Port.

Bit Range	Default & Access	Description
11	0b RO	**Reserved (RSVD):** Reserved.
10	0b RO	**IN_USE_CNT (INUSECNT_0):** Set by software to indicate that the port is in use. Cleared by software to indicate that the port is free and may be used by other software. This bit is cleared after reset. (This bit has no affect on hardware.)
9:7	000b RO	**EXCEPTION_STS (EXCP_STS_0):** Read-Only. This field indicates the exception when the ERROR_GOOD#_STS bit is set. This field should be ignored if the ERROR_GOOD#_STS bit is 0. 000 No Error. Note: this should not be seen, since this field should only be checked if there is an error. 001 Transaction error: indicates the USB2 transaction had an error (CRC, bad PID, time out, etc.) 010 HW error. Request was attempted (or in progress) when port was suspended or reset. All Others are reserved Reset default = 000b
6	0b RO	**ERROR_GOOD_STS (ERRGOODSTS_0):** Read-Only. The hardware clears this bit to 0 upon the proper completion of a read or write. The hardware sets this bit to indicate that an error has occurred. Details on the nature of the error are provided in the Exception field. Reset default = 0.
5	0b RW	**GO_CNT (GOCNT_0):** Software sets this bit to cause the hardware to perform a read or write request. Writing a 0 to this bit has no effect. Writing a 1 to this bit when it is already set may result in undefined behavior. When set, the hardware clears this bit when the hardware sets the DONE_STS bit. Reset default = 0.
4	0b RW	**WRITE_READ_CNT (WRRDCNT_0):** Software sets this bit to indicate that the current request is a write. Software clears this bit to indicate that the current request is a read. Reset default = 0.
3:0	0000b RW	**DATA_LEN_CNT (DATALENCNT_0):** This field is used to indicate the size of the data to be transferred. Reset default = 0h. For write operations, this field is set by software to indicate to the hardware how many bytes of data in Data Buffer are to be transferred to the console. A value of 0h indicates that a zero-length packet should be sent. A value of 1-8 indicates 1-8 bytes are to be transferred. Values 9-Fh are illegal and how hardware behaves if used is undefined. For read operations, this field is set by hardware to indicate to software how many bytes in Data Buffer are valid in response to a read operation. A value of 0h indicates that a zero length packet was returned and the state of Data Buffer is not defined. A value of 1-8 indicates 1-8 bytes were received. Hardware is not allowed to return values 9-Fh. The transferring of data always starts with byte 0 in the data area and moves toward byte 7 until the transfer size is reached.

Bit Range	Default & Access	Description
31:24	00h RO	**Reserved (RSVD):** Reserved.
23:16	00h RO	**RECEIVED_PID_STS (RECEIVED_PID_STS_0):** The hardware updates this field with the received PID for transactions in either direction. When the controller is writing data, this field is updated with the handshake PID that is received from the device. When the host controller is reading data, this field is updated with the data packet PID (if the device sent data), or the handshake PID (if the device NAKs the request). This field is valid when the hardware clears the GO_DONE#_CNT bit. Reset Default = 0.
15:8	00h RW	**SEND_PID_CNT (SEND_PID_CNT_0):** The hardware sends this PID to begin the data packet when sending data to USB (ie. WRITE_READ#_CNT is asserted). Software will typically set this field to either DATA0 or DATA1 PID values. Reset Default = 0
7:0	00h RW	**TOKEN_PID_CNT (TOKEN_PID_CNT_0):** The hardware sends this PID as the Token PID for each USB transaction. Software will typically set this field to either IN, OUT or SETUP PID values. Reset Default = 0.

Bit Range	Default & Access	Description
63:0	0000000000000000h RW	**DATABUFFER (DATABUFFER_0):** These are the 8 bytes of the data buffer. Bits 7:0 correspond to least significant byte (byte 0). Bits 63:56 correspond to the most significant byte (byte 7). The bytes in the Data Buffer must be written with data before software initiates a write request. For a read request, the Data Buffer contains valid data when DONE_STS is set by the hardware, ERROR_GOOD#_STS is cleared by the hardware, and the DATA_LENGTH_CNT field indicates the number of bytes that are valid. Reset Default = 0.

3.18.3 SSP Status Register (SSSR)—Offset 8h

The Enhanced SSP Status registers contain bits that signal overrun errors as well as the Transmit and Receive FIFO service requests. Each of these hardware-detected events signals an Interrupt request to the Interrupt controller. The Status register also contains flags that indicate when the Enhanced SSP is actively transmitting data, when the Transmit FIFO is not full, and when the Receive FIFO is not empty. One Interrupt signal is sent to the Interrupt Controller for each SSP. These events can cause an Interrupt: End-of-Chain, Receiver Time-out, Peripheral Trailing Byte, Receive FIFO overrun, Receive FIFO request, and Transmit FIFO request.

3.18.4 SSP Interrupt Test Register (SSITR)—Offset Ch

The read-write SSP Interrupt Test registers should be used only for testing purposes. Writing a 1 to the test transmit FIFO request SSITR.TTFS, bit 5, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Transmit FIFO. Writing a 1 to the test receive FIFO request SSITR.TRFS, bit 6, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Receive FIFO. Writing a 1 to the test receive FIFO overrun bit SSITR.TROR, bit 7, will generate a non-maskable Interrupt strobe signal to the Interrupt controller only, no DMA request will be made. Setting any of these bits will also cause the corresponding status bit(s) to be set in the Enhanced SSP Status

register (SSSR). The Interrupt and/or service request, caused by the setting of one of these test bits, will remain active until the test bit is cleared by writing a 0 it. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

3.18.5 SSP Data Register (SSDR)—Offset 10h

The Enhanced SSP Data registers are single address locations that Read-Write data transfers can access. The SSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO. As the system accesses the register, FIFO Control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted Write to a full Transmit FIFO). Status bits (such as SSSR.TFL, SSSR.RFL, SSSR.RNE, and SSSR.TNF) show users whether the FIFO is full, above/below a programmable FIFO trigger threshold, or empty. For Transmit data transfers (Write from system to SSP peripheral), the register can be loaded (written) by the system processor anytime it falls below its threshold level when using programmed I/O. When a data size of less than 32-bits is selected, users should not left-justify data written to the Transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data of less than 32-bits is automatically right-justified in the

Receive FIFO. When the Enhanced SSP is programmed for National Semiconductor Microwire* frame format and if the size for Transmit data is 8-bits as selected by SSCR1.MWDS=0, then the most significant 24-bits are ignored. Similarly, if the size for the Transmit data is 16-bit as selected by SSCR1.MWDS=1, then most significant 16-bits are ignored. The SSCR0.DSS field controls the Receive data size.

3.18.11 SSP Audio Clock Divider (SSACD)—Offset 3Ch

The Enhanced SSP Audio Clock Divider registers are read-write registers that indicate which clock frequency is sent to the Enhanced SSP and to the SYSCLK pin. If SSCR0.SCR is not 0, then there is no guaranteed phase relationship between SYSCLK and SSPSCLK. The SSPSFRM Frame Synch Sampling Frequency is calculated by dividing the chosen PLL output clock frequency (SSACD.ACPS) by the chosen divider (SSACD.ACDS) which gives the SYSCLK frequency. The SYSCLK is then divided by 4 (or by 1) to get the SSPSCLK. The SSPSCLK is divided by the data size (EDSS, DSS values) and by the number of time slots being used (SSCR0.FRDC value), if any, to give the SSPSFRM frequency. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined. It's important to note that this feature is only available if implemented by the project instantiation. A clock source and mux must be instantiated outside of the SSP controller for this feature to work. Only this register is designed into the SSP Controller.

3.19.3 SSP Status Register (SSSR)—Offset 8h

The Enhanced SSP Status registers contain bits that signal overrun errors as well as the Transmit and Receive FIFO service requests. Each of these hardware-detected events signals an Interrupt request to the Interrupt controller. The Status register also contains flags that indicate when the Enhanced SSP is actively transmitting data, when the Transmit FIFO is not full, and when the Receive FIFO is not empty. One Interrupt signal is sent to the Interrupt Controller for each SSP. These events can cause an Interrupt: End-of-Chain, Receiver Time-out, Peripheral Trailing Byte, Receive FIFO overrun, Receive FIFO request, and Transmit FIFO request.

3.19.4 SSP Interrupt Test Register (SSITR)—Offset Ch

The read-write SSP Interrupt Test registers should be used only for testing purposes. Writing a 1 to the test transmit FIFO request SSITR.TTFS, bit 5, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Transmit FIFO. Writing a 1 to the test receive FIFO request SSITR.TRFS, bit 6, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Receive FIFO. Writing a 1 to the test receive FIFO overrun bit SSITR.TROR, bit 7, will generate a non-maskable Interrupt strobe signal to the Interrupt controller only, no DMA request will be made. Setting any of these bits will also cause the corresponding status bit(s) to be set in the Enhanced SSP Status

register (SSSR). The Interrupt and/or service request, caused by the setting of one of these test bits, will remain active until the test bit is cleared by writing a 0 it. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

3.19.5 SSP Data Register (SSDR)—Offset 10h

The Enhanced SSP Data registers are single address locations that Read-Write data transfers can access. The SSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO. As the system accesses the register, FIFO Control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted Write to a full Transmit FIFO). Status bits (such as SSSR.TFL, SSSR.RFL, SSSR.RNE, and SSSR.TNF) show users whether the FIFO is full, above/below a programmable FIFO trigger threshold, or empty. For Transmit data transfers (Write from system to SSP peripheral), the register can be loaded (written) by the system processor anytime it falls below its threshold level when using programmed I/O. When a data size of less than 32-bits is selected, users should not left-justify data written to the Transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data of less than 32-bits is automatically right-justified in the

Receive FIFO. When the Enhanced SSP is programmed for National Semiconductor Microwire* frame format and if the size for Transmit data is 8-bits as selected by SSCR1.MWDS=0, then the most significant 24-bits are ignored. Similarly, if the size for the Transmit data is 16-bit as selected by SSCR1.MWDS=1, then most significant 16-bits are ignored. The SSCR0.DSS field controls the Receive data size.

3.19.11 SSP Audio Clock Divider (SSACD)—Offset 3Ch

The Enhanced SSP Audio Clock Divider registers are read-write registers that indicate which clock frequency is sent to the Enhanced SSP and to the SYSCLK pin. If SSCR0.SCR is not 0, then there is no guaranteed phase relationship between SYSCLK and SSPSCLK. The SSPSFRM Frame Synch Sampling Frequency is calculated by dividing the chosen PLL output clock frequency (SSACD.ACPS) by the chosen divider (SSACD.ACDS) which gives the SYSCLK frequency. The SYSCLK is then divided by 4 (or by 1) to get the SSPSCLK. The SSPSCLK is divided by the data size (EDSS, DSS values) and by the number of time slots being used (SSCR0.FRDC value), if any, to give the SSPSFRM frequency. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined. It's important to note that this feature is only available if implemented by the project instantiation. A clock source and mux must be instantiated outside of the SSP controller for this feature to work. Only this register is designed into the SSP Controller.

31:12	0b RO	**RSVD0:** Reserved
11	0b RW	**ASRC Interrupt Mask (ASRC_INTR_MASK):** Setting this bit to 1 masks the ASRC interrupt that is generated every time the frame count matches the frame threshold. Software should override this bit, since it have no reset value
10	0b RW	**ASRC frame count enable (ASRC_FRM_CNTR_EN):** Setting this bit enables the frame counter to start running. Clearing this bit will make the frame counter go back to zero immediately.
9	0b RW/AC	**ASRC Counter Clear (ASRC_CNTR_CLR):** Setting this to 1 will clear the ASRC Free running counter. This bit will self clear after the counter is cleared.
8	0b RW	**ASRC Counter enable (ASRC_CNTR_EN):** Setting this bit makes the Free running ASRC counter to start running. Clearing this bit will make it pause and hold it's current value.
7	1b RW	**Fifo empty fix enable (FIFO_EMPTY_FIX_EN):** Corner cases between the FIFO empty and APB writes happening to the TX FIFO around the time the new data needs to be sent out on the TXD are fixed with this bit.
6	1b RW	**Underrun fix enable (UNDRN_FIX_EN):** OSC to PLL switch along with underrun was causing unexpected behavior. This bit enables the fix for that bug.
5:4	00b RW	**Reserved:** This is a RW bit with no effect on IP behavior
3	0b RW	**Clock Delay Enable (CLK_DEL_EN):** When CLK_DEL_EN = 0, delay logic for capturing data from device is disabled. When CLK_DEL_EN = 1, delay logic for capturing data from device is delayed by half a period of the IO clock
2	0b RW	**Slave Mode External Clock Run Enable (SLV_EXT_CLK_RUN_EN):** When in Slave mode the receive state machine requires several clock edges (around 6) to properly sample incoming data. This bit enables a free running clock to the receive state machine before any data is received to properly sample the incoming data. 0 = Disable 1 = Enable

Bit Range	Default & Access	Description
1	0b RW	**Mode 1 Underrun Fix (Underrun_fix_1):** Mode 1 of transmit underrun fix. In this mode, new data will start on the underrun slot. This function is only appled to TI and PSP modes. 0 = disable mode 1 1 = enable mode 1 If both underrun modes are enable, mode 1 has higher priority.
0	0b RW	**Mode 0 Underrun Fix (Underrun_fix_0):** Mode 0 of transmit underrun fix. In this mode, new data will always start at slot 0. This function is only applied to TI and PSP modes. 0 = disable mode 1 1 = enable mode 1

3.19.13 SSP Frame Select Register (SSFS)—Offset 44h

The SSP Frame select register is used to choose which frame signal to assert when accessing a slave device. SW drivers should set this register to assert the correct frame select to the targeted device.

3.19.14 SSP Slot Frame Counter Register[0-7] (FRAME_CNT[0-7])—Offset 48h, Count 8, Stride 4h

The slot frame counter is typically used in Audio modes and increments the counter every two SSPSCLKs. This allows the OS to check the progress of a transfer. Since the SSP can support up to 8 slots in network mode there are 8 slot frame counters.

3.19.15 SSP FIFO Level Register (SFIFOL)—Offset 68h

The SFIFOL register describes the current state of the RX and TX FIFOs. Not all bits of the TFL and RFL fields are used and depends on the actual hardware FIFO depth used in the instantiation of the SSP controller. This FIFO level register is meant to replace the SSSR.TFL and SSR.RFL fields.

Access Method

15:0	0000h RO	**Transmit FIFO Level (TFL):** Number of entries in Transmit FIFO. Note: When the value 0x0 is read, the FIFO is either empty or full and the programmer should refer to the SSSR.TNF bit.

3.19.16 SSP FIFO Trigger Threshold Register (SFIFOTT)—Offset 6Ch

The SFIFOTT is a register that determines when the the FIFOs will assert an interrupt for FIFO full indication. This is meant to replace the SSCR1.RFT and SSCR1.TFT legacy registers. The max size of these registers is based on the actual FIFO depth in hardware and not the actual size of the bit field.

Bit Range	Default & Access	Description
31:16	0000h RW	**Receive FIFO Trigger Threshold (RFT):** Sets threshold level at which receive FIFO asserts interrupt. This level should be set to the desired threshold value minus 1. Notes on setting the RFT value. This applies to cases where SSP is receiving data from a device and is interfaced with a DMA channel via the hardware handshake mechanism. Please follow the following recommendations: 1. Number of bits denoted by the (DSS, EDSS) parameters in the SSP should match the SRC_TR_WIDTH programmed in the DMA channel. 2. (RFT+1) should be equal to (SRC_MSIZE). 3. Another option to 2 is to keep the BLOCK_TS in the DMA to be a multiple of (RFT+1)
15:0	0000h RW	**Transmit FIFO Trigger Threshold (TFT):** Sets threshold level at which transmit FIFO asserts interrupt. This level should be set to the desired threshold value minus 1.

3.19.17 SSP Control 3 Register (SSCR3)—Offset 70h

Software should only program this register if configuring the SSP in I2S/LJ mode or PCM master mode with the Tangier fixes. If neither is being enabled, SW can leave this register at the default power on value.

17	1b RW	**Sync Fix Enable (SYN_FIX_EN):** This is a chicken bit for enabling the synchronizer fix for clr_underrun_ssp signal. SW should preserve this bit at its default value.
16	0b RW	**Master Mode Clock Enable (MST_CLK_EN):** When in single slot master mode (which is the mode used for emulating I2S or LJ master mode), the SSP core can stop the clock on a Tx underflow condition, preventing the Rx side from receiving data. This bit, when set, forces the clock to run when a Tx underflow happens, thereby allowing Rx side to continue functioning while Tx side is in underflow. SW should set this bit when I2S or LJ master mode is enabled i.e. bits 0 and 1 in this register are both set or when using 1-slot PCM (SFS or LFS) master mode operation. Otherwise, SW should leave this at 0.
15	1b RW	**Stretch RX Pulse (STRETCH_RX):** HW uses this as a chicken bit to stretch the RX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.
14	1b RW	**Stretch TX Pulse (STRETCH_TX):** HW uses this as a chicken bit to stretch the TX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.

3.20.3 SSP Status Register (SSSR)—Offset 8h

The Enhanced SSP Status registers contain bits that signal overrun errors as well as the Transmit and Receive FIFO service requests. Each of these hardware-detected events signals an Interrupt request to the Interrupt controller. The Status register also contains flags that indicate when the Enhanced SSP is actively transmitting data, when the Transmit FIFO is not full, and when the Receive FIFO is not empty. One Interrupt signal is sent to the Interrupt Controller for each SSP. These events can cause an Interrupt: End-of-Chain, Receiver Time-out, Peripheral Trailing Byte, Receive FIFO overrun, Receive FIFO request, and Transmit FIFO request.

3.20.4 SSP Interrupt Test Register (SSITR)—Offset Ch

The read-write SSP Interrupt Test registers should be used only for testing purposes. Writing a 1 to the test transmit FIFO request SSITR.TTFS, bit 5, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Transmit FIFO. Writing a 1 to the test receive FIFO request SSITR.TRFS, bit 6, will generate a non-maskable Interrupt strobe signal to the Interrupt controller, and a DMA request for the Receive FIFO. Writing a 1 to the test receive FIFO overrun bit SSITR.TROR, bit 7, will generate a non-maskable Interrupt strobe signal to the Interrupt controller only, no DMA request will be made. Setting any of these bits will also cause the corresponding status bit(s) to be set in the Enhanced SSP Status

register (SSSR). The Interrupt and/or service request, caused by the setting of one of these test bits, will remain active until the test bit is cleared by writing a 0 it. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined.

3.20.5 SSP Data Register (SSDR)—Offset 10h

The Enhanced SSP Data registers are single address locations that Read-Write data transfers can access. The SSDR represents two physical registers: the first is temporary storage for data on its way out through the Transmit FIFO, the other is temporary storage for data coming in through the Receive FIFO. As the system accesses the register, FIFO Control logic transfers data automatically between register and FIFO as fast as the system moves it. Data in the FIFO shifts up or down to accommodate the new word (unless it's an attempted Write to a full Transmit FIFO). Status bits (such as SSSR.TFL, SSSR.RFL, SSSR.RNE, and SSSR.TNF) show users whether the FIFO is full, above/below a programmable FIFO trigger threshold, or empty. For Transmit data transfers (Write from system to SSP peripheral), the register can be loaded (written) by the system processor anytime it falls below its threshold level when using programmed I/O. When a data size of less than 32-bits is selected, users should not left-justify data written to the Transmit FIFO. Transmit logic left-justifies the data and ignores any unused bits. Received data of less than 32-bits is automatically right-justified in the

Receive FIFO. When the Enhanced SSP is programmed for National Semiconductor Microwire* frame format and if the size for Transmit data is 8-bits as selected by SSCR1.MWDS=0, then the most significant 24-bits are ignored. Similarly, if the size for the Transmit data is 16-bit as selected by SSCR1.MWDS=1, then most significant 16-bits are ignored. The SSCR0.DSS field controls the Receive data size.

3.20.11 SSP Audio Clock Divider (SSACD)—Offset 3Ch

The Enhanced SSP Audio Clock Divider registers are read-write registers that indicate which clock frequency is sent to the Enhanced SSP and to the SYSCLK pin. If SSCR0.SCR is not 0, then there is no guaranteed phase relationship between SYSCLK and SSPSCLK. The SSPSFRM Frame Synch Sampling Frequency is calculated by dividing the chosen PLL output clock frequency (SSACD.ACPS) by the chosen divider (SSACD.ACDS) which gives the SYSCLK frequency. The SYSCLK is then divided by 4 (or by 1) to get the SSPSCLK. The SSPSCLK is divided by the data size (EDSS, DSS values) and by the number of time slots being used (SSCR0.FRDC value), if any, to give the SSPSFRM frequency. Note that Writes to reserved bits must be zeroes, and Read value of these bits are undetermined. It's important to note that this feature is only available if implemented by the project instantiation. A clock source and mux must be instantiated outside of the SSP controller for this feature to work. Only this register is designed into the SSP Controller.

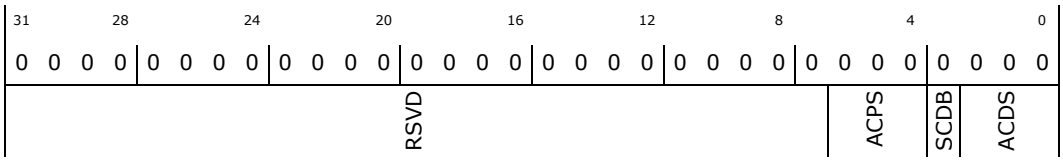
Default: 00000000h



Bit Range	Default & Access	Description
31:16	0000h RW	**Receive FIFO Trigger Threshold (RFT):** Sets threshold level at which receive FIFO asserts interrupt. This level should be set to the desired threshold value minus 1. Notes on setting the RFT value. This applies to cases where SSP is receiving data from a device and is interfaced with a DMA channel via the hardware handshake mechanism. Please follow the following recommendations: 1. Number of bits denoted by the (DSS, EDSS) parameters in the SSP should match the SRC_TR_WIDTH programmed in the DMA channel. 2. (RFT+1) should be equal to (SRC_MSIZE). 3. Another option to 2 is to keep the BLOCK_TS in the DMA to be a multiple of (RFT+1)
15:0	0000h RW	**Transmit FIFO Trigger Threshold (TFT):** Sets threshold level at which transmit FIFO asserts interrupt. This level should be set to the desired threshold value minus 1.

3.20.17 SSP Control 3 Register (SSCR3)—Offset 70h

Software should only program this register if configuring the SSP in I2S/LJ mode or PCM master mode with the Tangier fixes. If neither is being enabled, SW can leave this register at the default power on value.

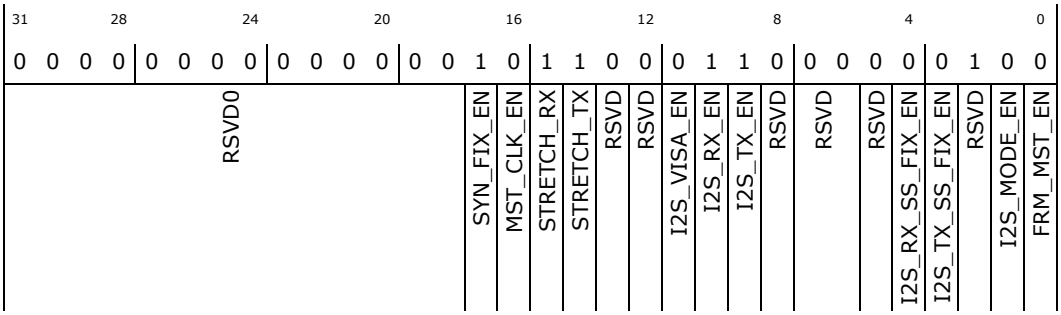
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SSCR3: [BAR + 0A2000h] + 70h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 0002C604h



Bit Range	Default & Access	Description
31:18	0b RO	**RSVD0:** Reserved
17	1b RW	**Sync Fix Enable (SYN_FIX_EN):** This is a chicken bit for enabling the synchronizer fix for clr_underrun_ssp signal. SW should preserve this bit at its default value.
16	0b RW	**Master Mode Clock Enable (MST_CLK_EN):** When in single slot master mode (which is the mode used for emulating I2S or LJ master mode), the SSP core can stop the clock on a Tx underflow condition, preventing the Rx side from receiving data. This bit, when set, forces the clock to run when a Tx underflow happens, thereby allowing Rx side to continue functioning while Tx side is in underflow. SW should set this bit when I2S or LJ master mode is enabled i.e. bits 0 and 1 in this register are both set or when using 1-slot PCM (SFS or LFS) master mode operation. Otherwise, SW should leave this at 0.
15	1b RW	**Stretch RX Pulse (STRETCH_RX):** HW uses this as a chicken bit to stretch the RX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.
14	1b RW	**Stretch TX Pulse (STRETCH_TX):** HW uses this as a chicken bit to stretch the TX pulse for proper clock crossing between SSP and APB domains. Note this bit is not tied to any specific SSP/PCM/I2S modes. SW should preserve this bit as the default value.
13	0b RO	**Reserved (RSVD):** Reserved.
12	0b RO	**Reserved (RSVD):** Reserved.
11	0b RW	**I2S VISA Enable (I2S_VISA_EN):** Enables newly added I2S and PCM wrapper logic debug signals sent out on the VISA bus instead of the core SSP debug signals. 0 = Core SSP Debug Signals 1 = New I2S and PCM Debug Signals

Bit Range	Default & Access	Description
10	1b RW	**I2S Receive Enable (I2S_RX_EN):** When set, this bit enables data to be received on both the left and right slots of I2S. Otherwise, data on the slots are ignored. HW does not signal FIFO full condition when this bit is cleared. SW can set/clear this bit dynamically when I2S mode is operational.
9	1b RW	**I2S Transmit Enable (I2S_TX_EN):** When set, this bit enables data to be transmitted on both the left and right slots of I2S. Otherwise, data on the slots are ignored. HW does not signal FIFO full condition when this bit is cleared. SW can set/clear this bit dynamically when I2S mode is operational.
8	0b RO	**Reserved (RSVD):** Reserved.
7:6	00b RO	**Reserved (RSVD):** Reserved.
5	0b RO	**Reserved (RSVD):** Reserved.
4	0b RW	**I2S RX Slot Swap Fix Enable (I2S_RX_SS_FIX_EN):** This bit enables the Rx overrun fix in I2S or LJ modes and prevents channel swapping when Rx overrun happens. Note that this bit does not apply to any PCM modes. PCM modes still have the Rx overflow channel aliasing issue, similar to PNW/CLV. SW should set this bit only when I2S or LJ mode (slave or master) is enabled. 0 = Disable 1 = Enable
3	0b RW	**I2S TX Slot Swap Fix Enable (I2S_TX_SS_FIX_EN):** This bit enables the TX underflow fix in I2S or LJ modes and prevents channel swapping when TX underflow happens. Note that this bit does not apply to any PCM modes. PCM modes still have the TX underflow channel aliasing issue, similar to PNW/CLV. SW should set this bit only when I2S or LJ mode (slave or master) is enabled. 0 = Disable 1 = Enable
2	1b RO	**Reserved (RSVD):** Reserved.
1	0b RW	**I2S Mode Enable (I2S_MODE_EN):** This bit enables I2S Mode. In I2S mode, slave or master mode operation is selected by appropriately clearing/setting bit 0 in this register. SW should select I2S mode operation before enabling the SSP controller. 0 = Disabled 1 = Enabled
0	0b RW	**Frame Master Enable (FRM_MST_EN):** When set, this bit enables the internal frame generator logic that allows accurate frame rate generation. This bit should be set for I2S and PCM master mode operations and cleared for all other modes. SW should select the proper value in this bit before enabling SSP controller. 0 = Disabled 1 = Enabled

3.20.18 SSP Control 4 Register (SSCR4)—Offset 74h

Software should only program this register if configuring the SSP in I2S/LJ mode or PCM master mode with the Tangier fixes. If neither is being enabled, SW can leave this register at the default power on value.

Access Method

31:16	0b RO	**RSVD0:** Reserved
15:7	000h RW	**Total Frame Period (TOT_FRM_PRD):** The total frame period (both asserted and de-asserted time of frame), measured in bit clocks, that is driven in I2S, LJ and PCM master modes. This can be controlled to get the desired accuracy on frame rate. A value of 0 and a value smaller than the value programmed in SSCR5.FrameAssertedWidth are illegal
6:0	00h RO	**Reserved (RSVD):** Reserved.

3.20.19 SSP Control 5 Register (SSCR5)—Offset 78h

Software should only program this register if configuring the SSP in I2S/LJ mode or PCM master mode with the Tangier fixes. If neither is being enabled, SW can leave this register at the default power on value.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

25:1	0000000h RW	**Frame Assert Width (FRM_ASRT_WIDTH):** This field controls the width of the asserted period of frame in I2S, LJ and PCM master modes. A value of 1 indicates a width of 2 bit clock period, 2 indicates a width of 3 bit clock periods, etc. The frame width is Frame Assert Width + 1.
0	0b RO	**Reserved (RSVD):** Reserved.

3.20.20 ASRC Free Running Timer (ASRC_FRT)—Offset 7Ch

This is a 32 bit free running counter that can be enabled, paused or cleared using bits in the SSCR2_XR register. The value reflected here will be noted down in the timer snapshot register when the frame count matches the frame threshold

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

ASRC_FRT: [BAR + 0A2000h] + 7Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

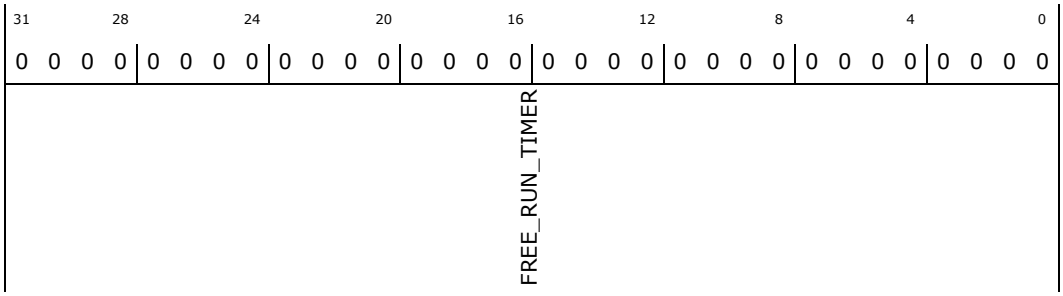
Default: 00000000h



Bit Range	Default & Access	Description
31:0	00000000h RO/V	**ASRC free running timer (FREE_RUN_TIMER):** This field reflects the value of the free running timer.

3.20.21 Frame Threshold for ASRC Frame Count (ASRC_FTC)—Offset 80h

The frame threshold value at which the timer snapshot will be taken is written here.

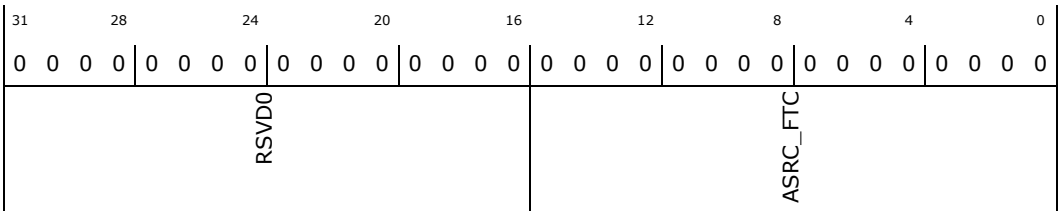
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

ASRC_FTC: [BAR + 0A2000h] + 80h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:16	0b RO	**RSVD0:** Reserved
15:0	0000h RW	**ASRC Frame Threshold (ASRC_FTC):** The 16 bit frame threshold value needs to be written here. Every time the frame count matches the frame threshold a snapshot of the free running timer will be taken and stored in the snapshot register. An interrupt will be generated as well. If the frame threshold is changed on the fly during operation then the following behavior is expected. Previous value = A, New value value = B If B) A : The frame counter keeps counting up to the new value. Nothing happens when the frame counter reaches the old value of A. If B (A : The frame counter resets to zero on the next frame. No interrupt or snapshot is generated in this case.

3.20.22 ASRC Timer Snapshot (ASRC_SNPSHT)—Offset 84h

Frame Snapshot Register

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

ASRC_SNPSHT: [BAR + 0A2000h] + 84h

BAR Type: PCI Configuration Register (Size: 32 bits)

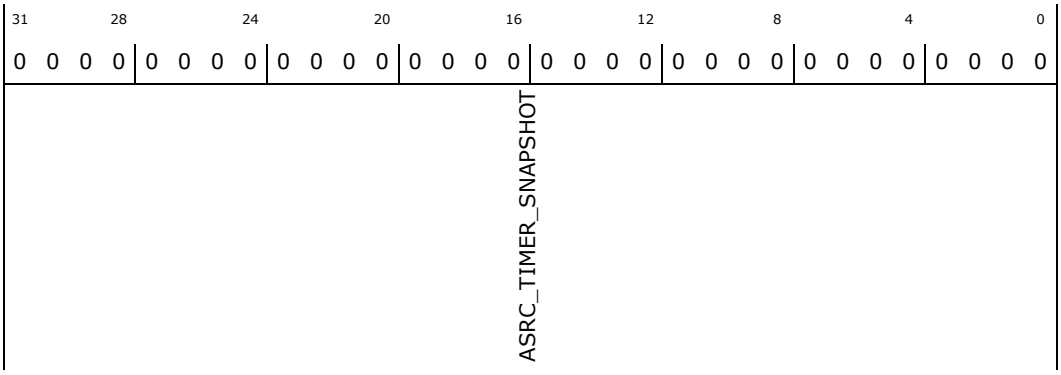
Default: 00000000h



Bit Range	Default & Access	Description
31:0	00000000h RO	**ASRC Frame Snapshot (ASRC_TIMER_SNAPSHOT):** This field holds the 32 bit snapshot value. The value is noted on the clock cycle when the frame threshold matches the frame count.

3.20.23 ASRC Frame Count (ASRC_FRMCNT)—Offset 88h

Frame Count Register

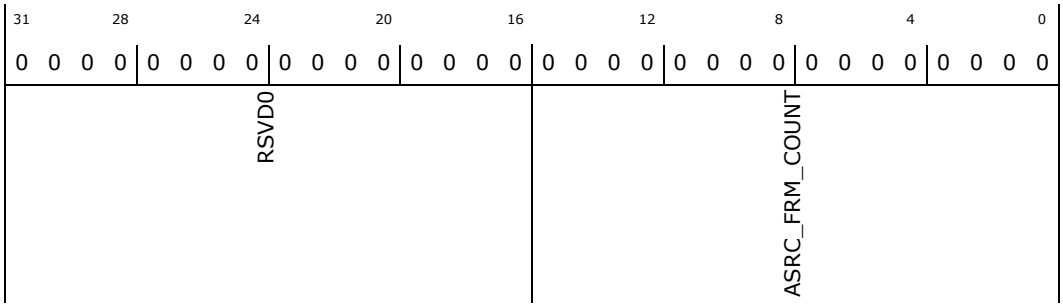
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

ASRC_FRMCNT: [BAR + 0A2000h] + 88h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:16	0b RO	**RSVD0:** Reserved
15:0	0000h RO	**ASRC Frame Count (ASRC_FRM_COUNT):** This is the current frame count. This is a debug register and the value is noted in this register only when the LSB of the frame counter flips. If the counter is cleared when it was at an even value, the cleared value is not reflected here.

3.21.1 reg_SAR_type (SAR0)—Offset 0h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

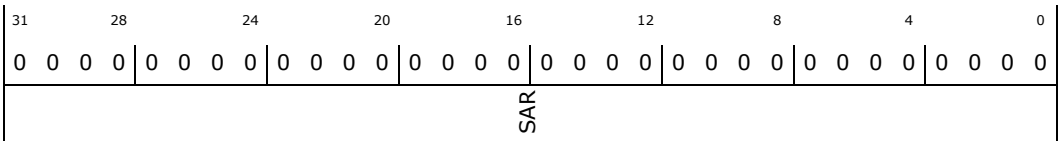
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR0: [BAR + 98000h] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.21.2 reg_DAR_type (DAR0)—Offset 8h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

31:0	0h RW	**DAR:** Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.21.3 reg_LLP_type (LLP0)—Offset 10h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

Access Method

Bit Range	Default & Access	Description
31:2	00000000h RW	**LOC:** Starting Address In Memory of next LLI if block chaining is enabled. Note that the two LSBs of the starting address are not stored because the address is assumed to be aligned to a 32-bit boundary. LLI accesses are always 32-bit accesses and cannot be changed or programmed to anything other than 32-bit.
1:0	0h RO	**RSVD2:** Reserved

3.21.4 reg_CTL_LO_type (CTL_LO0)—Offset 18h

This register contains fields that control the DMA transfer.The CTL_LO register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

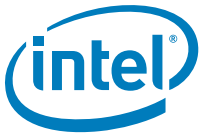
Bit Range	Default & Access	Description
31:29	0h RO	**RSVD:** Reserved
28	0h RW	**LLP_SRC_EN:** Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	**LLP_DST_EN:** Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	**RSVD1:** RSVD
21:20	0h RW	**TT_FC:** Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	**RSVD2:** Reserved



Bit Range	Default & Access	Description
18	0h RW	**DST_SCATTER_EN:** Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	**SRC_GATHER_EN:** Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	**SRC_MSIZE:** Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	**DEST_MSIZE:** Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	**SINC:** Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)
9	0h RO	**RSVD3:** Reserved
8	0h RW	**DINC:** Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	**RSVD4:** Reserved
6:4	0h RW	**SRC_TR_WIDTH:** Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	**DST_TR_WIDTH:** Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1.Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2.For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	**INT_EN:** Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

3.21.5 reg_CTL_HI_type (CTL_HI0)—Offset 1Ch

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

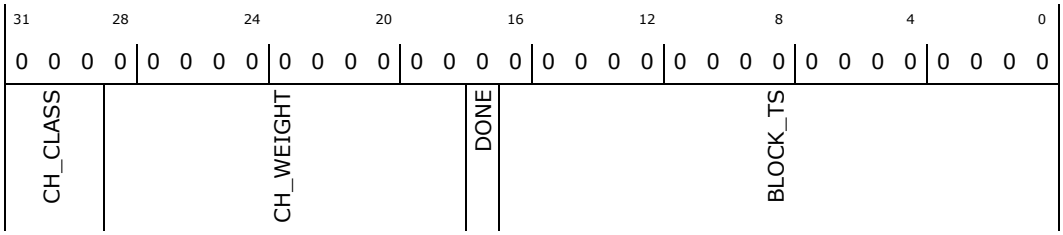
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL_HI0: [BAR + 98000h] + 1Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.21.6 reg_SSTAT_type (SSTAT0)—Offset 20h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

The source status information should be retrieved by software from the SSTATn register location of the LLI, and not by a read of this register over the DMA slave interface.

3.21.7 reg_DSTAT_type (DSTAT0)—Offset 28h

After the completion of each block transfer, hardware can retrieve the destination status information from the address pointed to by the contents of the DSTATARx register. This status information is then stored in the DSTATx register and written out to the DSTATx register location of the LLI. Note : This register is a temporary placeholder for the destination status information on its way to the DSTATx register location of the LLI. 3.21.12 reg_SGR_type (SGR0)—Offset 48h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

3.21.14 reg_SAR_type (SAR1)—Offset 58h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

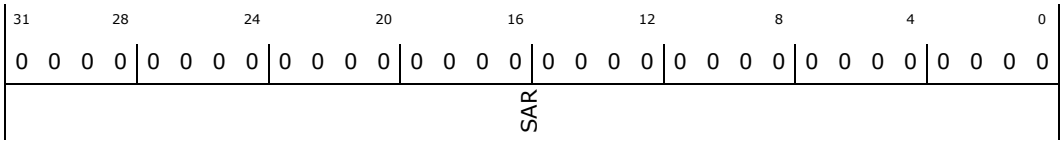
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR1: [BAR + 98000h] + 58h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.21.15 reg_DAR_type (DAR1)—Offset 60h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

3.21.16 reg_LLP_type (LLP1)—Offset 68h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

3.21.18 reg_CTL_HI_type (CTL_HI1)—Offset 74h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

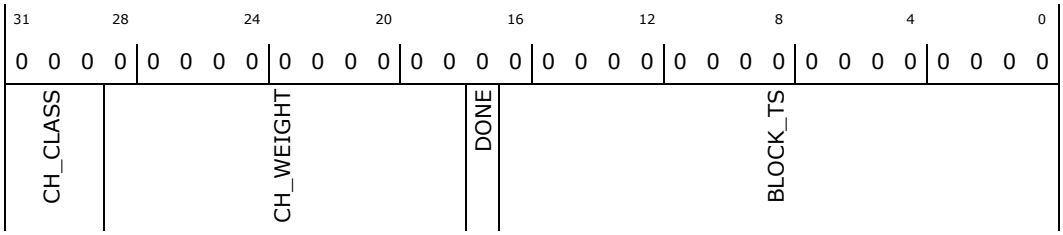
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL_HI1: [BAR + 98000h] + 74h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.

Bit Range	Default & Access	Description
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.21.19 reg_SSTAT_type (SSTAT1)—Offset 78h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

3.21.25 reg_SGR_type (SGR1)—Offset A0h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

3.21.27 reg_SAR_type (SAR2)—Offset B0h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

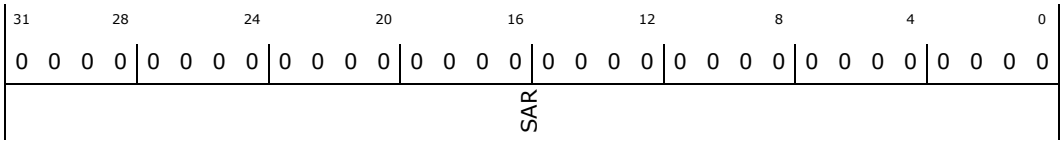
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR2: [BAR + 98000h] + B0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.21.28 reg_DAR_type (DAR2)—Offset B8h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

3.21.29 reg_LLP_type (LLP2)—Offset C0h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

3.21.31 reg_CTL_HI_type (CTL_HI2)—Offset CCh

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

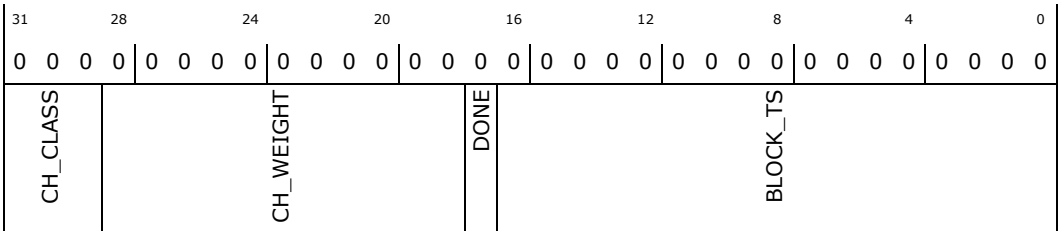
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL_HI2: [BAR + 98000h] + CCh

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.21.32 reg_SSTAT_type (SSTAT2)—Offset D0h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

3.21.38 reg_SGR_type (SGR2)—Offset F8h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

3.21.40 reg_SAR_type (SAR3)—Offset 108h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

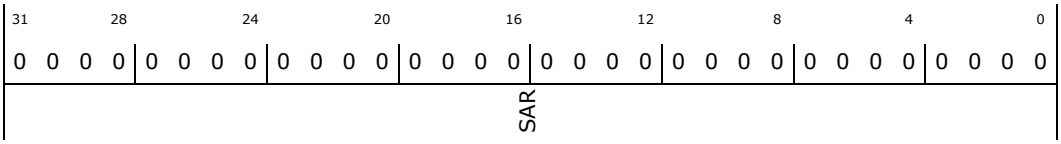
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR3: [BAR + 98000h] + 108h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.21.41 reg_DAR_type (DAR3)—Offset 110h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. 3.21.42 reg_LLP_type (LLP3)—Offset 118h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

3.21.44 reg_CTL_HI_type (CTL_HI3)—Offset 124h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

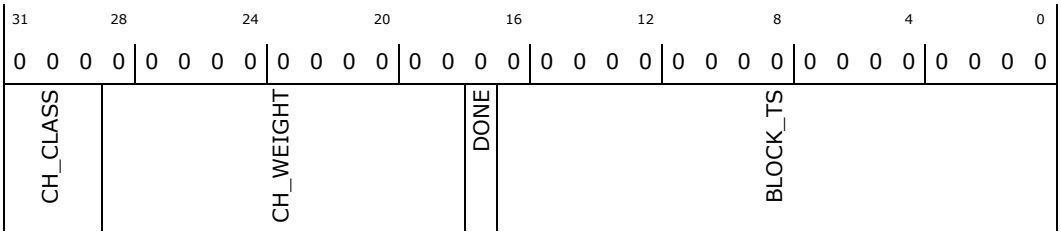
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL_HI3: [BAR + 98000h] + 124h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.

Bit Range	Default & Access	Description
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.21.45 reg_SSTAT_type (SSTAT3)—Offset 128h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

3.21.51 reg_SGR_type (SGR3)—Offset 150h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

3.21.52 reg_DSR_type (DSR3)—Offset 158h

The Destination Scatter register contains two fields: Destination scatter count field (DSRx.DSC) . Specifies the number of contiguous destination transfers of CTLx.DST_TR_WIDTH between successive scatter boundaries. Destination scatter interval field (DSRx.DSI) . Specifies the destination address increment/decrement in multiples of CTLx.DST_TR_WIDTH on a scatter boundary when scatter mode is enabled for the destination transfer. The CTLx.DINC field controls whether the address increments or decrements. When the CTLx.DINC field indicates a fixed address control, then the address remains constant throughout the transfer and the DSRx register is ignored.

3.21.53 reg_SAR_type (SAR4)—Offset 160h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

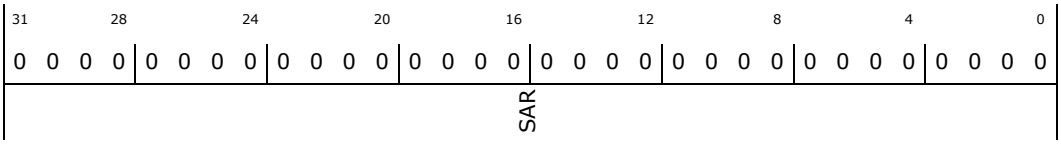
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR4: [BAR + 98000h] + 160h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.21.54 reg_DAR_type (DAR4)—Offset 168h

3.21.55 reg_LLP_type (LLP4)—Offset 170h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

3.21.57 reg_CTL_HI_type (CTL_HI4)—Offset 17Ch

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

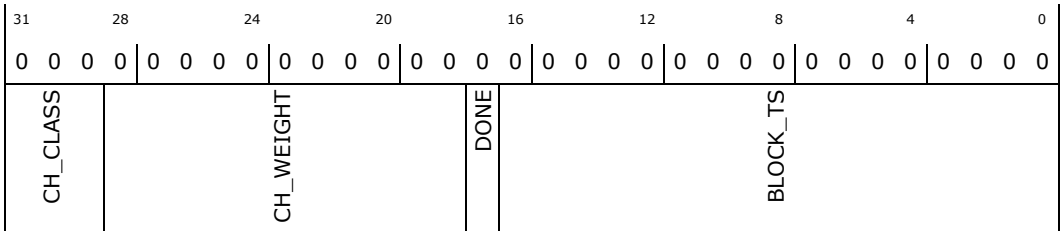
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL_HI4: [BAR + 98000h] + 17Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.21.58 reg_SSTAT_type (SSTAT4)—Offset 180h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

3.21.66 reg_SAR_type (SAR5)—Offset 1B8h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

Access Method

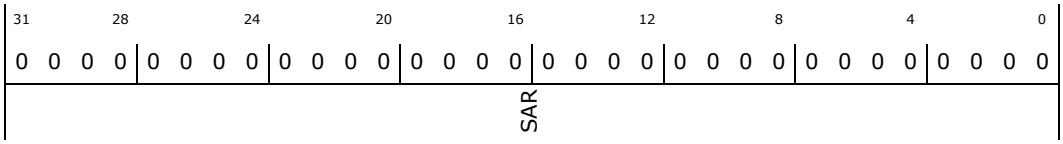
SAR5: [BAR + 98000h] + 1B8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.21.67 reg_DAR_type (DAR5)—Offset 1C0h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

3.21.68 reg_LLP_type (LLP5)—Offset 1C8h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.

Bit Range	Default & Access	Description
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.21.71 reg_SSTAT_type (SSTAT5)—Offset 1D8h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

3.21.77 reg_SGR_type (SGR5)—Offset 200h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

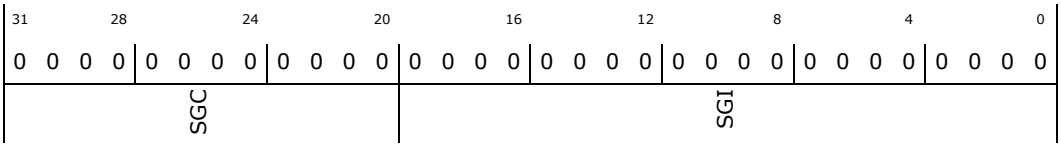
BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.21.80 reg_DAR_type (DAR6)—Offset 218h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

Bit Range	Default & Access	Description
31:0	0h RW	**DAR:** Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. 3.21.81 reg_LLP_type (LLP6)—Offset 220h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

3.21.83 reg_CTL_HI_type (CTL_HI6)—Offset 22Ch

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

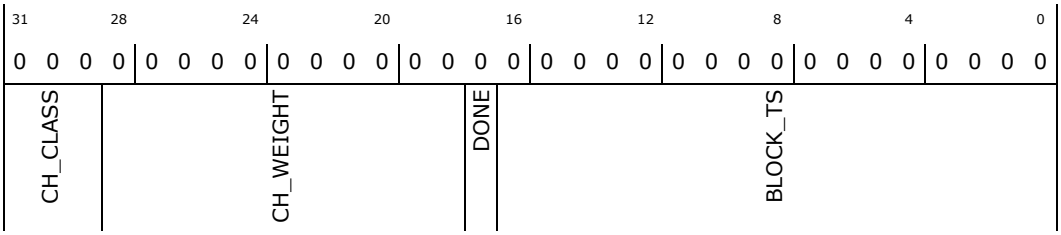
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL_HI6: [BAR + 98000h] + 22Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.21.84 reg_SSTAT_type (SSTAT6)—Offset 230h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

3.21.90 reg_SGR_type (SGR6)—Offset 258h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

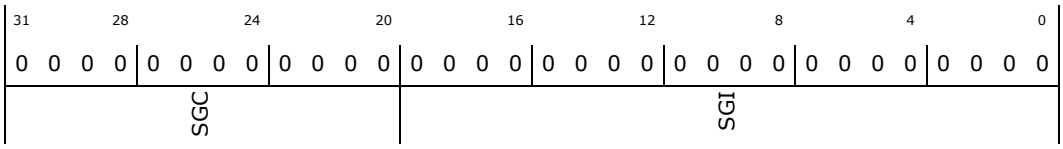
BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

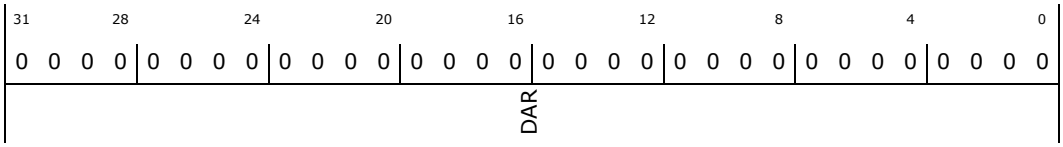
BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**DAR:** Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.21.94 reg_LLP_type (LLP7)—Offset 278h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

27	0h RW	**LLP_DST_EN:** Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	**RSVD1:** RSVD
21:20	0h RW	**TT_FC:** Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	**RSVD2:** Reserved
18	0h RW	**DST_SCATTER_EN:** Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	**SRC_GATHER_EN:** Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	**SRC_MSIZE:** Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	**DEST_MSIZE:** Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	**SINC:** Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)
9	0h RO	**RSVD3:** Reserved
8	0h RW	**DINC:** Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. 3.21.96 reg_CTL_HI_type (CTL_HI7)—Offset 284h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

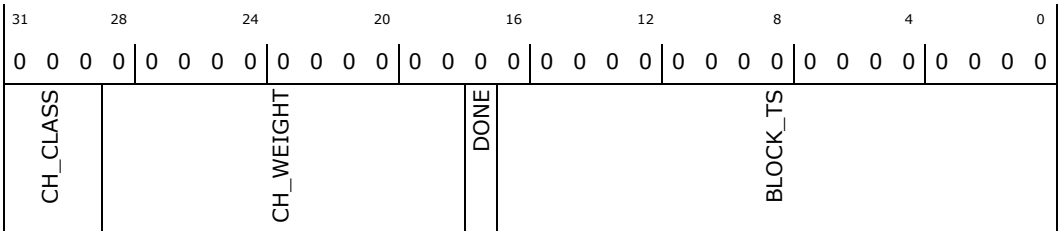
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL_HI7: [BAR + 98000h] + 284h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.

Bit Range	Default & Access	Description
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.21.97 reg_SSTAT_type (SSTAT7)—Offset 288h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

3.21.115 reg_Mask_type (MaskTfr)—Offset 310h

The contents of the Raw Status registers are masked with the contents of the Mask registers: MaskBlock, MaskDstTran, MaskErr, MaskSrcTran, and MaskTfr. Each Interrupt Mask register has a bit allocated per channel, for example, MaskTfr(2) is the mask bit for the Channel 2 transfer complete interrupt. When the source peripheral of DMA

channel i is memory, then the source transaction complete interrupt, MaskSrcTran(i), must be masked to prevent an erroneous triggering of an interrupt on the int_combined signal. Similarly, when the destination peripheral of DMA channel i is memory, then the destination transaction complete interrupt, MaskDstTran(i), must be masked to prevent an erroneous triggering of an interrupt on the int_combined(_n) signal. A channel INT_MASK bit will be written only if the corresponding mask write enable bit in the INT_MASK_WE field is asserted on the same OCP write transfer. This allows software to set a mask bit without performing a read-modified write operation. For example, writing hex 01x1 to the MaskTfr register writes a 1 into MaskTfr(0), while MaskTfr(7:1) remains unchanged. Writing hex 00xx leaves MaskTfr(7:0) unchanged. Writing a 1 to any bit in these registers unmasks the corresponding interrupt, thus allowing the DMA to set the appropriate bit in the Status registers and int_* port signals.

Similarly, when the destination peripheral of DMA channel i is memory, then the destination transaction complete interrupt, MaskDstTran(i), must be

masked to prevent an erroneous triggering of an interrupt on the int_combined(_n) signal. A channel INT_MASK bit will be written only if the corresponding mask write enable bit in the INT_MASK_WE field is asserted on the same OCP write transfer. This allows software to set a mask bit without performing a read-modified write operation. For example, writing hex 01x1 to the MaskTfr register writes a 1 into MaskTfr(0), while MaskTfr(7:1) remains unchanged. Writing hex 00xx leaves MaskTfr(7:0) unchanged. 3.21.127 reg_ChEnReg_type (ChEnReg)—Offset 3A0h

This is the DMA Channel Enable Register. If software needs to set up a new channel, then it can read this register in order to find out which channels are currently inactive, it can then enable an inactive channel with the required priority. All bits of this register are cleared to 0 when the global DMA channel enable bit, DmaCfgReg(0), is 0. When the global channel enable bit is 0, then a write to the ChEnReg register is ignored and a read will always read back 0. The channel enable bit, ChEnReg.CH_EN, is written only if the corresponding channel write enable bit, ChEnReg.CH_EN_WE, is asserted on the same OCP write transfer. For example, writing hex 01x1 writes a 1 into ChEnReg(0), while ChEnReg(7:1) remains unchanged. Writing hex 00xx leaves ChEnReg(7:0) unchanged. Note that a read-modified write is not required.

3.22.1 reg_SAR_type (SAR0)—Offset 0h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

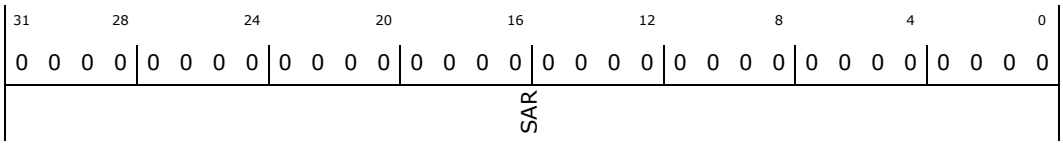
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR0: [BAR + 9C000h] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.22.2 reg_DAR_type (DAR0)—Offset 8h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

31:0	0h RW	**DAR:** Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.22.3 reg_LLP_type (LLP0)—Offset 10h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

3.22.4 reg_CTL_LO_type (CTL_LO0)—Offset 18h

This register contains fields that control the DMA transfer.The CTL_LO register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

31:29	0h RO	**RSVD:** Reserved
28	0h RW	**LLP_SRC_EN:** Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	**LLP_DST_EN:** Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	**RSVD1:** RSVD
21:20	0h RW	**TT_FC:** Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	**RSVD2:** Reserved

Bit Range	Default & Access	Description
18	0h RW	**DST_SCATTER_EN:** Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	**SRC_GATHER_EN:** Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	**SRC_MSIZE:** Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	**DEST_MSIZE:** Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	**SINC:** Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)
9	0h RO	**RSVD3:** Reserved
8	0h RW	**DINC:** Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. 6:4	0h RW	**SRC_TR_WIDTH:** Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	**DST_TR_WIDTH:** Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1.Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2.For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	**INT_EN:** Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

3.22.5 reg_CTL_HI_type (CTL_HI0)—Offset 1Ch

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

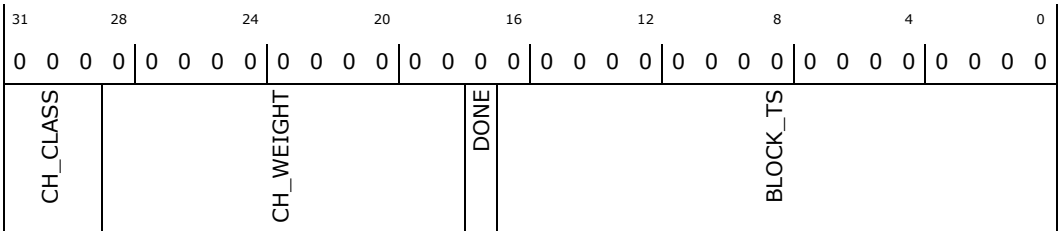
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL_HI0: [BAR + 9C000h] + 1Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.22.6 reg_SSTAT_type (SSTAT0)—Offset 20h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

The source status information should be retrieved by software from the SSTATn register location of the LLI, and not by a read of this register over the DMA slave interface.

3.22.7 reg_DSTAT_type (DSTAT0)—Offset 28h

After the completion of each block transfer, hardware can retrieve the destination status information from the address pointed to by the contents of the DSTATARx register. This status information is then stored in the DSTATx register and written out to the DSTATx register location of the LLI. Note : This register is a temporary placeholder for the destination status information on its way to the DSTATx register location of the LLI. 3.22.12 reg_SGR_type (SGR0)—Offset 48h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

The Destination Scatter register contains two fields: Destination scatter count field (DSRx.DSC) . Specifies the number of contiguous destination transfers of CTLx.DST_TR_WIDTH between successive scatter boundaries. Destination scatter interval field (DSRx.DSI) . Specifies the destination address increment/decrement in multiples of CTLx.DST_TR_WIDTH on a scatter boundary when scatter mode is enabled for the destination transfer. The CTLx.DINC field controls whether the address increments or decrements. When the CTLx.DINC field indicates a fixed address control, then the address remains constant throughout the transfer and the DSRx register is ignored.

3.22.14 reg_SAR_type (SAR1)—Offset 58h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

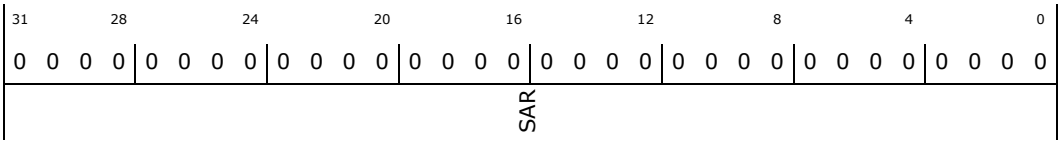
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR1: [BAR + 9C000h] + 58h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.22.15 reg_DAR_type (DAR1)—Offset 60h

3.22.16 reg_LLP_type (LLP1)—Offset 68h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

3.22.18 reg_CTL_HI_type (CTL_HI1)—Offset 74h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.

Bit Range	Default & Access	Description
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.22.19 reg_SSTAT_type (SSTAT1)—Offset 78h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

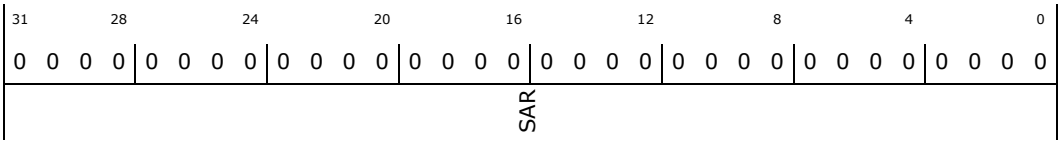
SAR2: [BAR + 9C000h] + B0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.22.28 reg_DAR_type (DAR2)—Offset B8h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

Bit Range	Default & Access	Description
31:0	0h RW	**DAR:** Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.22.29 reg_LLP_type (LLP2)—Offset C0h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

Bit Range	Default & Access	Description
31:2	00000000h RW	**LOC:** Starting Address In Memory of next LLI if block chaining is enabled. Note that the two LSBs of the starting address are not stored because the address is assumed to be aligned to a 32-bit boundary. LLI accesses are always 32-bit accesses and cannot be changed or programmed to anything other than 32-bit.
1:0	0h RO	**RSVD2:** Reserved

3.22.30 reg_CTL_LO_type (CTL_LO2)—Offset C8h

This register contains fields that control the DMA transfer.The CTL_LO register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

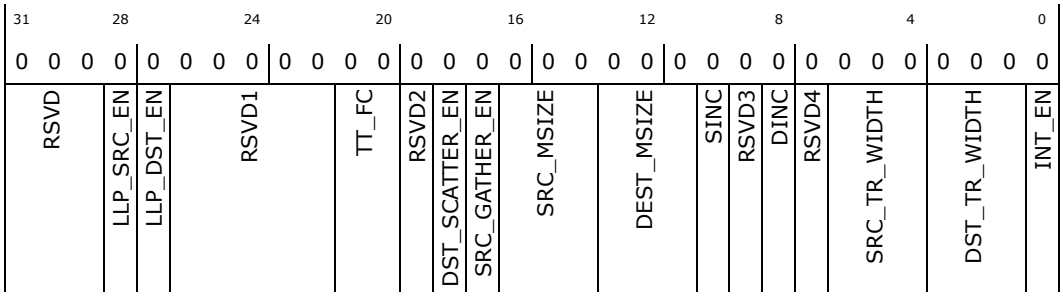
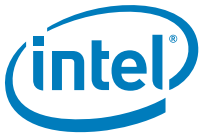
Default: 00000000h



Bit Range	Default & Access	Description
31:29	0h RO	**RSVD:** Reserved
28	0h RW	**LLP_SRC_EN:** Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
27	0h RW	**LLP_DST_EN:** Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPn.LOC is non-zero and (LLP_EN == 1)
26:22	0h RO	**RSVD1:** RSVD
21:20	0h RW	**TT_FC:** Transfer Type and Flow Control. The following transfer types are supported. Memory to Memory (00) Memory to Peripheral (01) Peripheral to Memory (10) Peripheral to Peripheral (11) Flow Control is always assigned to the DMA.
19	0h RO	**RSVD2:** Reserved



Bit Range	Default & Access	Description
18	0h RW	**DST_SCATTER_EN:** Destination scatter enable bit: 0 = Scatter disabled 1 = Scatter enabled Scatter on the destination side is applicable only when the CTL_LOn.DINC bit indicates an incrementing address control.
17	0h RW	**SRC_GATHER_EN:** Source gather enable bit: 0 = Gather disabled 1 = Gather enabled Gather on the source side is applicable only when the CTL_LOn.SINC bit indicates an incrementing address control.
16:14	0h RW	**SRC_MSIZE:** Source Burst Transaction Length. Number of data items, each of width CTL_LOn.SRC_TR_WIDTH, to be read from the source. TABLE 5-1 talks about the encoding for this field.
13:11	0h RW	**DEST_MSIZE:** Destination Burst Transaction Length. Number of data items, each of width CTL_LOn.DST_TR_WIDTH, to be written to the destination. TABLE 5-1 talks about the encoding for this field.
10	0h RW	**SINC:** Source Address Increment. Indicates whether to increment or decrement the source address on every source transfer. If the device is fetching data from a source peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No Change)
9	0h RO	**RSVD3:** Reserved
8	0h RW	**DINC:** Destination Address Increment. Indicates whether to increment or decrement the destination address on every destination transfer. If your device is writing data to a destination peripheral FIFO with a fixed address, then set this field to No change. 0 = Increment 1 = Fixed (No change)
7	0h RO	**RSVD4:** Reserved
6:4	0h RW	**SRC_TR_WIDTH:** Source Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1. Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2. For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
3:1	0h RW	**DST_TR_WIDTH:** Destination Transfer Width. BURST_SIZE = (2 ^ MSIZE) 1.Transferred Bytes Per Burst = (BURST_SIZE * TR_WIDTH) 2.For incrementing addresses and (Transfer_Width (4 Bytes), the MSIZE parameter is ignored since only single transactions are supported (due to OCP limitations) Table 5-2 lists the decoding for this field. For a non-memory peripheral, this is typically the peripheral (source) FIFO width.
0	0h RW	**INT_EN:** Interrupt Enable Bit. If set, then all interrupt-generating sources are enabled.

3.22.31 reg_CTL_HI_type (CTL_HI2)—Offset CCh

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

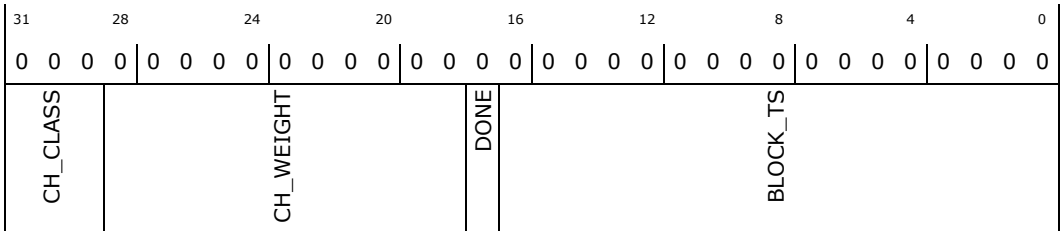
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL_HI2: [BAR + 9C000h] + CCh

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.22.32 reg_SSTAT_type (SSTAT2)—Offset D0h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

31:0	0h RW	**SSTAT:** Source status information retrieved by hardware from the address pointed to by the contents of the Source Status Address Register. This register is a temporary placeholder for the source status information on its way to the SSTATn register location of the LLI. The source status information should be retrieved by software from the SSTATn register location of the LLI, and not by a read of this register over the DMA slave interface.

3.22.33 reg_DSTAT_type (DSTAT2)—Offset D8h

After the completion of each block transfer, hardware can retrieve the destination status information from the address pointed to by the contents of the DSTATARx register. This status information is then stored in the DSTATx register and written out to the DSTATx register location of the LLI. Note : This register is a temporary placeholder for the destination status information on its way to the DSTATx register location of the LLI. The destination status information should be retrieved by software from the DSTATx register location of the LLI and not by a read of this register over the DMA slave interface.

3.22.38 reg_SGR_type (SGR2)—Offset F8h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

3.22.40 reg_SAR_type (SAR3)—Offset 108h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current transfer.

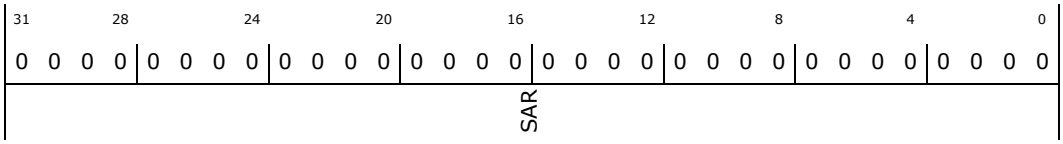
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR3: [BAR + 9C000h] + 108h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.22.41 reg_DAR_type (DAR3)—Offset 110h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current transfer.

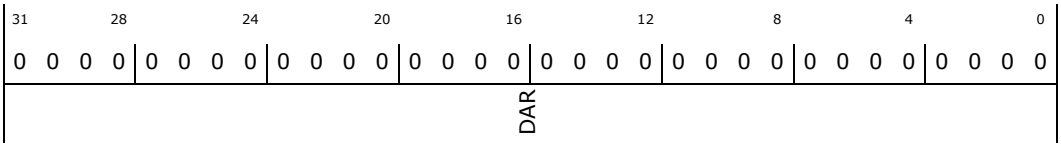
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

DAR3: [BAR + 9C000h] + 110h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**DAR:** Current Destination Address of DMA transfer. Updated after each destination transfer. The DINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every destination transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.22.42 reg_LLP_type (LLP3)—Offset 118h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

3.22.44 reg_CTL_HI_type (CTL_HI3)—Offset 124h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

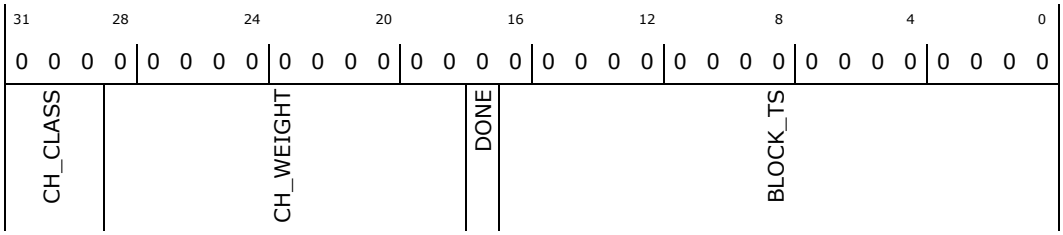
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL_HI3: [BAR + 9C000h] + 124h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.

Bit Range	Default & Access	Description
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.22.45 reg_SSTAT_type (SSTAT3)—Offset 128h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated destination transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Write Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Write address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA write was a burst write (i.e. burst length) 1), the read-back value reflects the first address of the burst write since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA write progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.22.55 reg_LLP_type (LLP4)—Offset 170h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

3.22.57 reg_CTL_HI_type (CTL_HI4)—Offset 17Ch

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Access Method

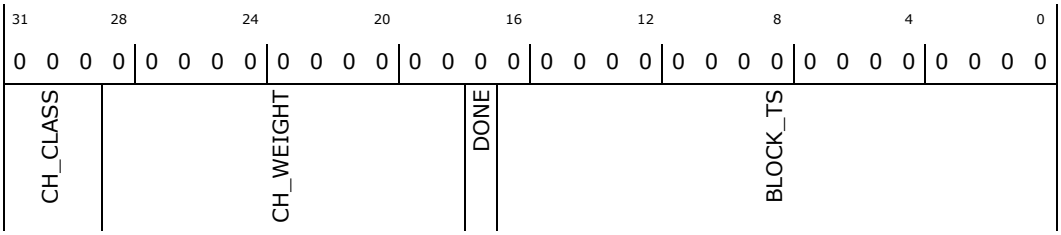
CTL_HI4: [BAR + 9C000h] + 17Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.22.58 reg_SSTAT_type (SSTAT4)—Offset 180h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

BAR Type: PCI Configuration Register (Size: 32 bits)

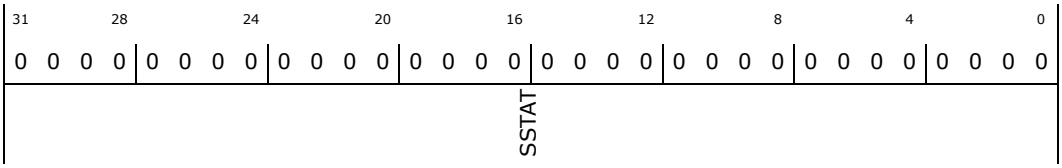
Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.22.68 reg_LLP_type (LLP5)—Offset 1C8h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

3.22.70 reg_CTL_HI_type (CTL_HI5)—Offset 1D4h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.

Bit Range	Default & Access	Description
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.22.71 reg_SSTAT_type (SSTAT5)—Offset 1D8h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.22.83 reg_CTL_HI_type (CTL_HI6)—Offset 22Ch

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

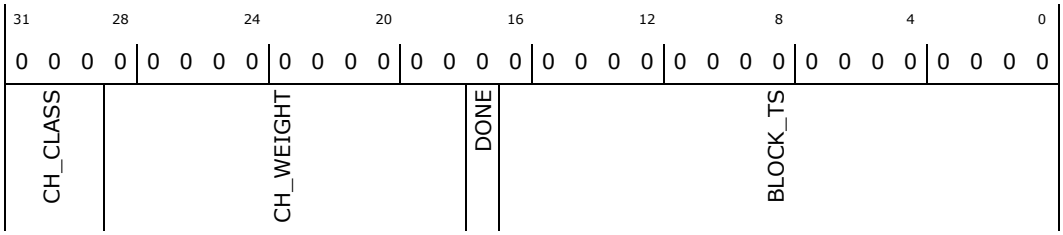
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL_HI6: [BAR + 9C000h] + 22Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.22.84 reg_SSTAT_type (SSTAT6)—Offset 230h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

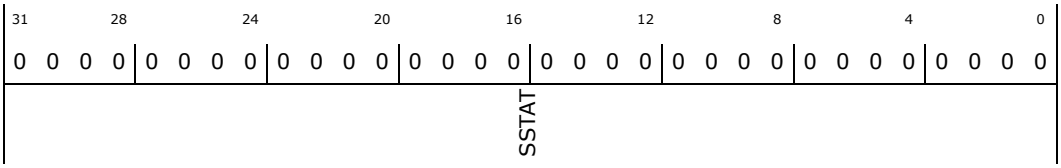
Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTL_LO[n]: Control Register determines whether the address increments or is left unchanged on every source transfer throughout the block transfer. When the channel is enabled (i.e. CH_EN is 1), the read back value will reflect the updated source transfer addresses. However, when the channel is disabled, the original programmed value will be reflected when reading this register. It's important to notice the following: 1. Once the block transfer is in progress (i.e. when channel is enabled), the read-back value correlates with the OCP Read Address that one would see in an OCP tracker. 2. If the read to this register comes during a block transfer, the LAST DMA Read address sent on the OCP before the register read is what's reflected in the read-back value. 3. If the last DMA read was a burst read (i.e. burst length) 1), the read-back value reflects the first address of the burst read since this is what gets sent on the OCP fabric. 4. If the read to the register occurred after the whole block got transferred, then the channel gets disabled and the returned value would be the original programmed value. 5. Since the read-back value is OCP based, only DW aligned addresses will be reflected (i.e. OCP Byte-Enable values would not be reflected) 6. Based on the above remarks, this value should be used as pseudo DMA read progress indicator when the channel is enabled and not an absolute one. Decrementing addresses are not supported

3.22.94 reg_LLP_type (LLP7)—Offset 278h

Note: You need to program this register to point to the first Linked List Item (LLI) in memory prior to enabling the channel if block chaining is enabled The LLP register has two functions: The logical result of the equation LLP.LOC != 0 is used to set up the type of DMA transfer-single or multi-block. Table shows how the method of updating the channel registers is a function of LLP.LOC != 0. If LLP.LOC is set to 0x0, then transfers using linked lists are not enabled. This register must be programmed prior to enabling the channel in order to set up the transfer type. LLP.LOC != 0 contains the pointer to the next LLI for block chaining using linked lists, The LLPx register can also point to the address where write-back of the control and source/destination status information occur after block completion.

3.22.96 reg_CTL_HI_type (CTL_HI7)—Offset 284h

This register contains fields that control the DMA transfer. The CTL_HI register is part of the block descriptor (linked list item - LLI) when block chaining is enabled. It can be varied on a block-by-block basis within a DMA transfer when block chaining is enabled.If status write-back is enabled, CTL_HI is written to then control registers location of the LLI in system memory at the end of the block transfer.

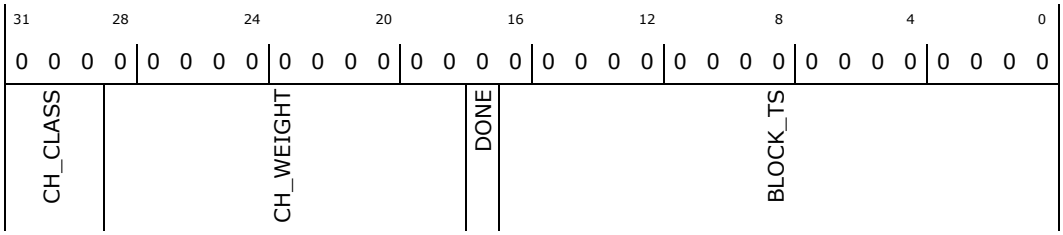
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL_HI7: [BAR + 9C000h] + 284h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:21, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:29	0h RW	**CH_CLASS:** Channel Class. A Class of (N_CHNLS-1) is the highest priority, and 0 is the lowest. This field must be programmed within 0 to (N_CHNLS-1). A programmed value outside this range will cause erroneous behavior. ** See restriction in CH_WEIGHT below
28:18	0h RW	**CH_WEIGHT:** Channel Weight : Value of K assigns a weight of (K+1) in the round-robin arbitration between channels of the same class. A value of 0x7FF assigns an arbitration weight of 2048. Since K is from 0 to (2^11-1)=2047, Arbitration Weight ranges from 1 to 2048 **Restrictions : 1. CH_CLASS and CH_WEIGHT cannot be changed on the fly. Changes to either values for ANY channel require that ALL channels be quiescent in order to propagate those changes to the read and write arbiters without affecting their functionality. 2. Another possible way of achieving the quiescence requirement is to suspend ALL channels before changing the CH_CLASS and CH_WEIGHT. 3. Caution must be taken in descriptor-based (linked-list) multi-block transfers since the LLI.CTL_HI is one of the DW that needs to be read and loaded into the CTL_HI internal register. Hence, user needs to ensure that the CH_CLASS and CH_WEIGHT fields do not change from one descriptor to another nor do they disturb the aforementioned quiescence requirement.

Bit Range	Default & Access	Description
17	0h RW	**DONE:** If status write-back is enabled, the upper word of the control register, CTL_HIn, is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTL_HI.DONE bit to see when a block transfer is complete. The LLI CTL_HI.DONE bit should be cleared when the linked lists are set up in memory prior to enabling the channel. The DMA will not transfer the block if the DONE bit in the LLI is not cleared.
16:0	0h RW	**BLOCK_TS:** Block Transfer Size (in Bytes). Since the DMA is always the flow controller, the user needs to write this field before the channel is enabled in order to indicate the block size. The number programmed into BLOCK_TS indicates the total number of bytes to transfer for every block transfer. Once the transfer starts (i.e. channel is enabled), the read-back value is the total number of bytes for which Read Commands have already been sent to the source. It does not mean Bytes that are already in the FIFO. However, when the channel is disabled, the original programmed value will be reflected when reading this register. Theoretical Byte Size range is from 0 to (2^17 -1) = (128 KB - 1).

3.22.97 reg_SSTAT_type (SSTAT7)—Offset 288h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Note : This register is a temporary placeholder for the source status information on its way to the SSTATx register location of the LLI. The source status information should be retrieved by software from the SSTATx register location of the LLI, and not by a read of this register over the DMA slave interface.

3.22.103 reg_SGR_type (SGR7)—Offset 2B0h

The Source Gather register contains two fields: Source gather count field (SGRx.SGC). Specifies the number of contiguous source transfers of CTLx.SRC_TR_WIDTH between successive gather intervals. This is defined as a gather boundary. Source gather interval field (SGRx.SGI). Specifies the source address increment/decrement in multiples of CTLx.SRC_TR_WIDTH on a gather boundary when gather mode is enabled for the source transfer. The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored.

3.22.112 reg_Status_type (StatusSrcTran)—Offset 2F8h

All interrupt events from all channels are stored in these Interrupt Status registers after masking: statusBlock, StatusDstTran, StatusErr, StatusSrcTran, and StatusTfr. Each Interrupt Status register has a bit allocated per channel, for example, StatusTfr(2) is the Channel 2 status transfer complete interrupt. The contents of these registers are used to generate the interrupt signals (int or int_n bus, depending on interrupt polarity) leaving the DMA.

3.22.115 reg_Mask_type (MaskTfr)—Offset 310h

The contents of the Raw Status registers are masked with the contents of the Mask registers: MaskBlock, MaskDstTran, MaskErr, MaskSrcTran, and MaskTfr. Each Interrupt Mask register has a bit allocated per channel, for example, MaskTfr(2) is the mask bit for the Channel 2 transfer complete interrupt. When the source peripheral of DMA

channel i is memory, then the source transaction complete interrupt, MaskSrcTran(i), must be masked to prevent an erroneous triggering of an interrupt on the int_combined signal. Similarly, when the destination peripheral of DMA channel i is memory, then the destination transaction complete interrupt, MaskDstTran(i), must be masked to prevent an erroneous triggering of an interrupt on the int_combined(_n) signal. A channel INT_MASK bit will be written only if the corresponding mask write enable bit in the INT_MASK_WE field is asserted on the same OCP write transfer. This allows software to set a mask bit without performing a read-modified write operation. For example, writing hex 01x1 to the MaskTfr register writes a 1 into MaskTfr(0), while MaskTfr(7:1) remains unchanged. Writing hex 00xx leaves MaskTfr(7:0) unchanged. Writing a 1 to any bit in these registers unmasks the corresponding interrupt, thus allowing the DMA to set the appropriate bit in the Status registers and int_* port signals.

The contents of the Raw Status registers are masked with the contents of the Mask registers: MaskBlock, MaskDstTran, MaskErr, MaskSrcTran, and MaskTfr. Each Interrupt Mask register has a bit allocated per channel, for example, MaskTfr(2) is the mask bit for the Channel 2 transfer complete interrupt. Similarly, when the destination peripheral of DMA channel i is memory, then the destination transaction complete interrupt, MaskDstTran(i), must be

masked to prevent an erroneous triggering of an interrupt on the int_combined(_n) signal. A channel INT_MASK bit will be written only if the corresponding mask write enable bit in the INT_MASK_WE field is asserted on the same OCP write transfer. This allows software to set a mask bit without performing a read-modified write operation. For example, writing hex 01x1 to the MaskTfr register writes a 1 into MaskTfr(0), while MaskTfr(7:1) remains unchanged. Writing hex 00xx leaves MaskTfr(7:0) unchanged. 3.22.127 reg_ChEnReg_type (ChEnReg)—Offset 3A0h

This is the DMA Channel Enable Register. If software needs to set up a new channel, then it can read this register in order to find out which channels are currently inactive, it can then enable an inactive channel with the required priority. All bits of this register are cleared to 0 when the global DMA channel enable bit, DmaCfgReg(0), is 0. When the global channel enable bit is 0, then a write to the ChEnReg register is ignored and a read will always read back 0. The channel enable bit, ChEnReg.CH_EN, is written only if the corresponding channel write enable bit, ChEnReg.CH_EN_WE, is asserted on the same OCP write transfer. For example, writing hex 01x1 writes a 1 into ChEnReg(0), while ChEnReg(7:1) remains unchanged. Writing hex 00xx leaves ChEnReg(7:0) unchanged. Note that a read-modified write is not required.

3.23.8 reg_IPCX_type (IPCX)—Offset 38h

The Inter-process Status and Message register for IA-32 contains a message sent from the IA-32 CPU to LPE. The format of the CPU message bits (61:0) is not defined in the HW specs. It is defined in the LPE Firmware specifications. The message may contain optional data fields stored in the shared memory region (mailbox). When the message is written in this register, the software must set bit 63 to indicate that the IPCIA is not empty. Setting Busy also asserts interrupt request to LPE if the interrupt is enabled in the IMRLPEIA. After LPE reads the message code from the register, it must perform a write with bit 63 cleared. The IA-32 CPU must not attempt to write into IPCIA if bit 63 is set.

3.23.9 reg_IPCD_type (IPCD)—Offset 40h

Inter-process Status and Message register for LPE contains a message sent from LPE to IA-32 CPU. The format of the CPU message bits 29:0 is defined in the LPE Firmware specifications. The message may contain optional data fields stored in the shared memory region (mailbox). When software writes the message is in this register, it should set bit 63 to indicate that the new data is written. When IA-32 CPU reads the

message code from the register, and writes back with the bit 63 cleared. When the IA-32 CPU processes the message sent by LPE, it may set bit 63 in IPCD to assert interrupt request to LPE. The LPE must not attempt to write into IPCLPEIA if bit 63 is set.

3.23.14 reg_IPCSC_type (IPCSC)—Offset 68h

The Inter-process Status and Message register for SC contains a message sent from the SC CPU to LPE. The format of the CPU message bits (29:0) is not defined in the HW specs. It is defined in the LPE Firmware specifications. The message may contain optional data fields stored in the shared memory region (mailbox). When the message is written in this register, the software must set bit 63 to indicate that the IPCSC is not empty. Setting Busy also asserts interrupt request to LPE if the interrupt is enabled in the IMRLPESC. After LPE reads the message code from the register, it must perform a write with bit 63 cleared. The SC CPU must not attempt to write into IPCIA if bit 63 is set.

3.23.15 reg_IPCLPESC_type (IPCLPESC)—Offset 70h

Inter-process Status and Message register for LPE contains a message sent from LPE to SC. The format of the CPU message bits 29:0 is defined in the LPE Firmware specifications. The message may contain optional data fields stored in the shared memory region (mailbox). When software writes the message is in this register, it should set bit 63 to indicate that the new data is written. When SC reads the message code from the register, and writes back with the bit 63 cleared. When the SC CPU processes the message sent by LPE, it may set bit 62 in IPCLPESC to assert interrupt request to LPE. The LPE must not attempt to write into IPCD if bit 63 is set.

3.24.3 reg_REVCLASSCODE_type (REVCLASSCODE)—Offset 8h

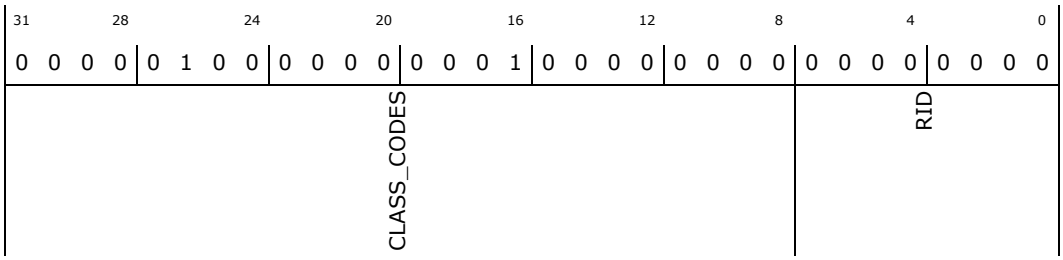
REVCLASSCODE - Revision ID and Class Code

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

REVCLASSCODE: [0/21/0] + 8h

Default: 04010000h



Bit Range	Default & Access	Description
31:8	040100h RO	**CLASS_CODES:** Class Code
7:0	00h RO	**RID:** Revision ID

3.24.4 reg_CLLATHEADERBIST_type (CLLATHEADERBIST)—Offset Ch

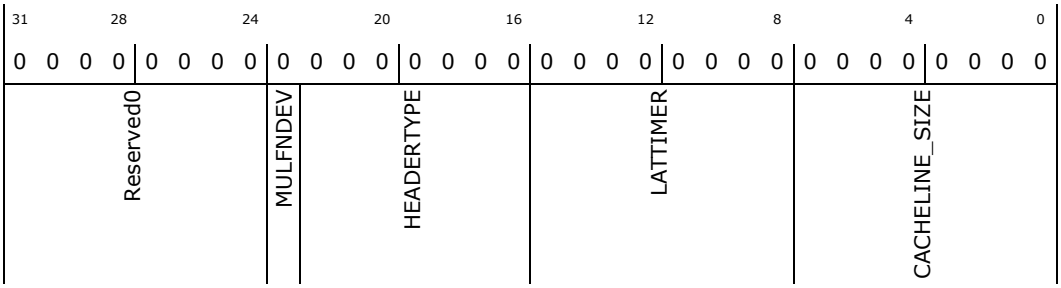
CLLATHEADERBIST - Cache Line Latency Header and BIST

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CLLATHEADERBIST: [0/21/0] + Ch

Default: 00000000h



Bit Range	Default & Access	Description
31:24	00h RO	**Reserved0:** Reserved
23	0h RO	**MULFNDEV:** MULFNDEV
22:16	00h RO	**HEADERTYPE:** Header Type: Implements Type 0 Configuration header.
15:8	00h RO	**LATTIMER:** Latency Timer:. This register is implemented as R/W with default as 0. Similar to other Intel IPs.
7:0	00h RW	**CACHELINE_SIZE:** Cacheline Size: This register is implemented as R/W with default as 0. Similar to other Intel IPs.

3.24.5 reg_BAR_type (BAR)—Offset 10h

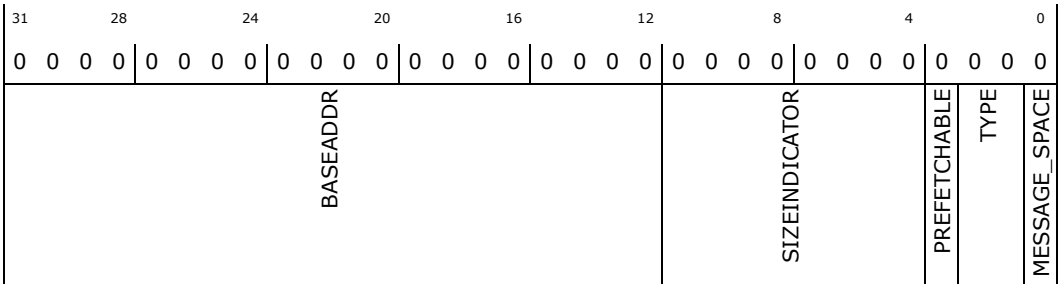
BAR -Base Address Register

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR: [0/21/0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:12	00000h RW	**BASEADDR:** Base Address register
11:4	00h RO	**SIZEINDICATOR:** Size indicator
3	0h RO	**PREFETCHABLE:** Indicates that this BAR is not prefetchable.
2:1	0h RO	**TYPE:** 00 indicates BAR lies in 32bit address range
0	0h RO	**MESSAGE_SPACE:** message space

3.24.6 reg_BAR1_type (BAR1)—Offset 14h

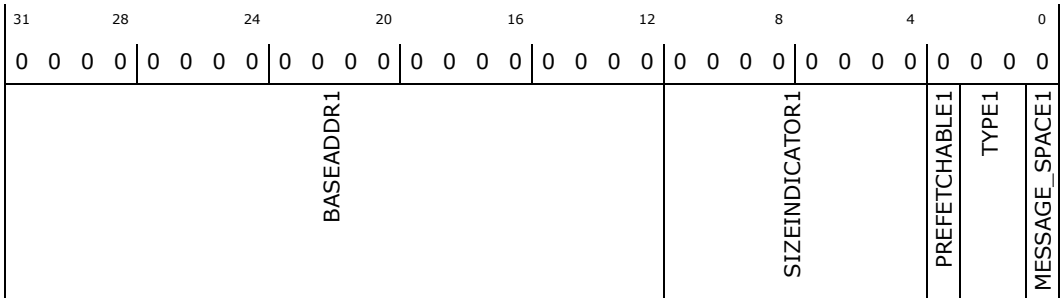
BAR1 -Base Address Register1

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

BAR1: [0/21/0] + 14h

Default: 00000000h



Bit Range	Default & Access	Description
31:12	00000h RW	**BASEADDR1:** This field is present if BAR1 is enabled through private configuration space. Memory accesses to BAR1 region are aliased to the PCI configuration space. The BAR1 region is always 4K.
11:4	00h RO	**SIZEINDICATOR1:** Always is 0 as minimum size is 4K
3	0h RO	**PREFETCHABLE1:** Indicates that this BAR is not prefetchable
2:1	0h RO	**TYPE1:** 00 indicates BAR lies in 32bit address range
0	0h RO	**MESSAGE_SPACE1:** message space

3.24.7 reg_SUBSYSTEMID_type (SUBSYSTEMID)—Offset 2Ch

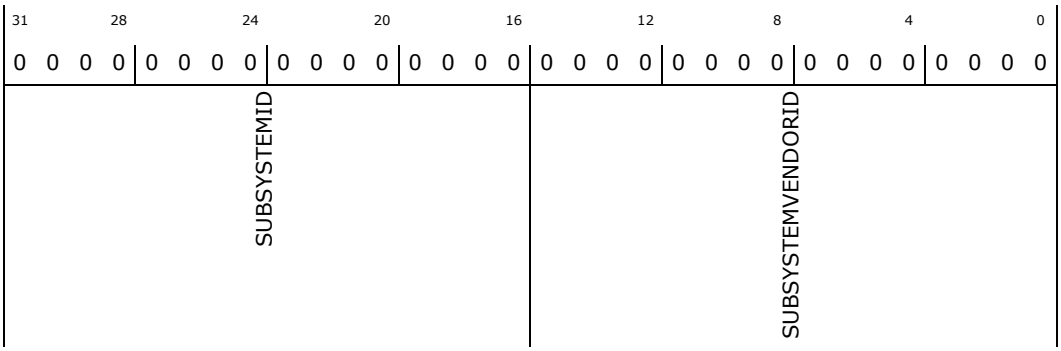
SUBSYSTEMID -Subsystem Vendor and Subsystem ID

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SUBSYSTEMID: [0/21/0] + 2Ch

Default: 00000000h



Bit Range	Default & Access	Description
31:16	0000h RW/O	**SUBSYSTEMID:** Subsystem ID
15:0	0000h RW/O	**SUBSYSTEMVENDORID:** Subsystem Vendor

3.24.8 reg_EXPANSION_ROM_BASEADDR_type (EXPANSION_ROM_BASEADDR)—Offset 30h

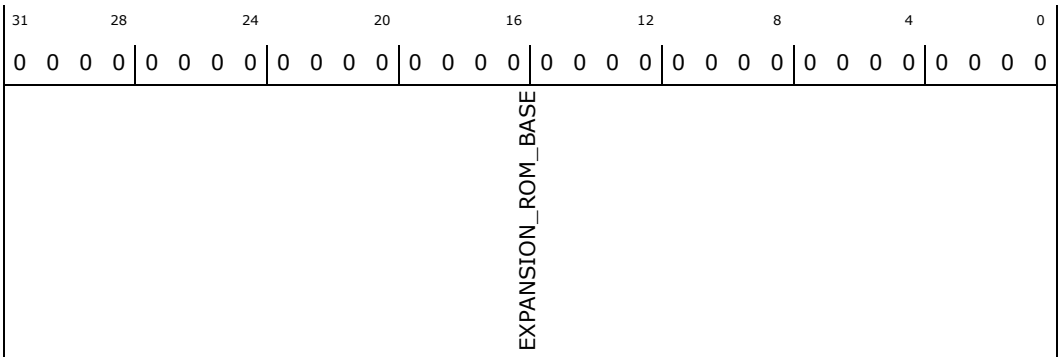
EXPANSION ROM base address

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

EXPANSION_ROM_BASEADDR: [0/21/0] + 30h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	00000000h RO	**EXPANSION_ROM_BASE:** Value of all zeros indicates no support for Expansion ROM

3.24.9 reg_CAPABILITYPTR_type (CAPABILITYPTR)—Offset 34h

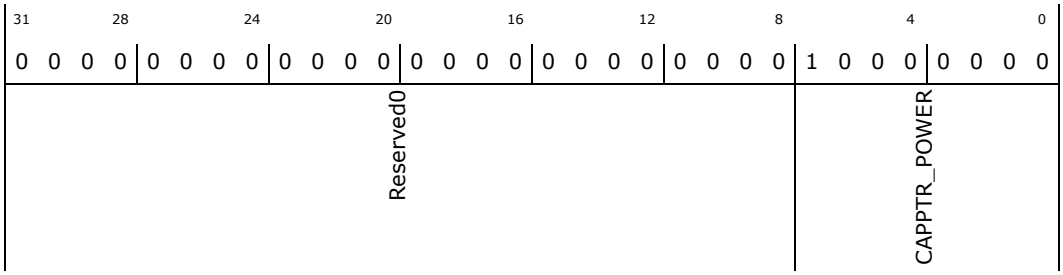
CAPABILITYPTR - Capabilities Pointer

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CAPABILITYPTR: [0/21/0] + 34h

Default: 00000080h



Bit Range	Default & Access	Description
31:8	000000h RO	**Reserved0:** reserved
7:0	80h RO	**CAPPTR_POWER:** Indicates what the next capability is. This capability points to the PM Capability, 0x80, structure.

3.24.10 reg_INTERRUPTREG_type (INTERRUPTREG)—Offset 3Ch

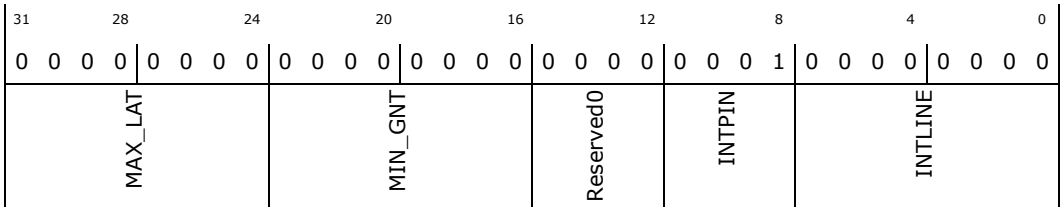
INTERRUPTREG - Interrupt Register

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

INTERRUPTREG: [0/21/0] + 3Ch

Default: 00000100h



Bit Range	Default & Access	Description
31:24	00h RO	**MAX_LAT:** Value of 0 indicates device has no major requirements for the settings of latency timers
23:16	00h RO	**MIN_GNT:** Value of 0 indicates device has no major requirements for the settings of latency timers
15:12	0h RO	**Reserved0:** reserved
11:8	1h RO	**INTPIN:** Interrupt Pin Value in this register is reflected from the IPIN value in the private configuration space. For a single function device, this ideally is INTA
7:0	00h RW	**INTLINE:** Bridge does not use this field directly. It is used to communicate to software, the interrupt line to which the interrupt pin is connected.

3.24.11 reg_POWERCAPID_type (POWERCAPID)—Offset 80h

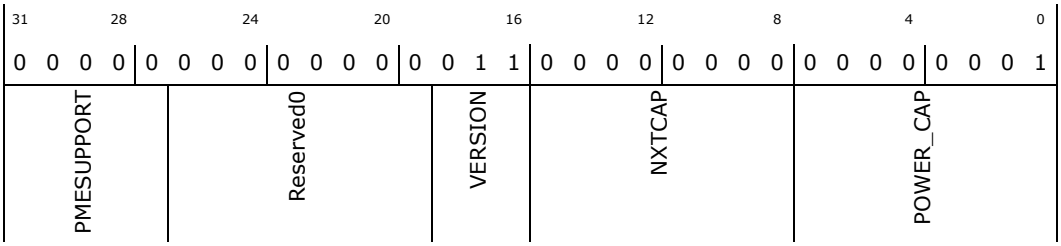
POWERCAPID - PowerManagement Capability ID

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

POWERCAPID: [0/21/0] + 80h

Default: 00030001h



Bit Range	Default & Access	Description
31:27	00h RO	**PMESUPPORT:** This 5-bit field indicates the power states in which the function can assert the PME#. A value of 0b for any bit indicates that the function is not capable of asserting the PME# signal at the same time in that power state. bit 11 X XXX1b: PME# can be asserted from D0 bit 12 X XX1Xb: PME# can be asserted from D1. Bridge does not support this state. bit 13 X X1XXb: PME# can be asserted from D2. Bridge does not support this state. bit 14 X 1XXXb:PME# can be asserted from D3hot bit 15 1 XXXXb:PME# can be asserted from D3cold. Bridge does not support this state. This field is taken from the private configuration space PME_Support XORed with the PME_Support strap.
26:19	00h RO	**Reserved0:** reserved
18:16	3h RO	**VERSION:** Indicates support for Revision 1.2 of the PCI Power Management Specification.
15:8	00h RO	**NXTCAP:** Points to the next capability structure. This points to NULL

Bit Range	Default & Access	Description
7:0	01h RO	**POWER_CAP:** Indicates this is power management capability.

3.24.12 reg_PMECTRLSTATUS_type (PMECTRLSTATUS)—Offset 84h

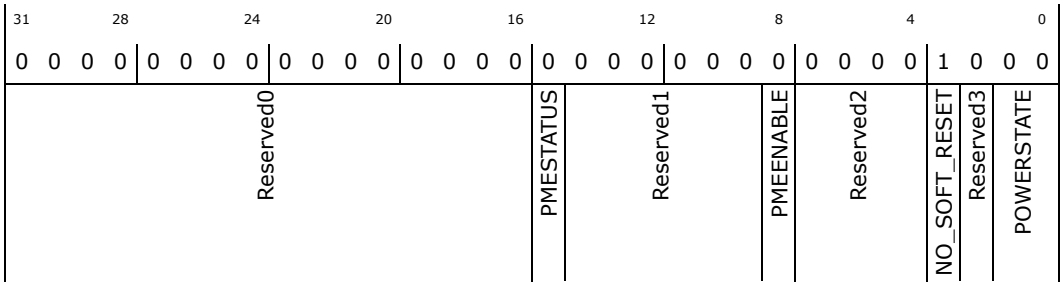
reserved

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

PMECTRLSTATUS: [0/21/0] + 84h

Default: 00000008h



Bit Range	Default & Access	Description
31:16	0000h RO	**Reserved0:** reserved
15	0h RW/1C	**PMESTATUS:** 0 Software clears the bit by writing a 1 to it. 1 This bit is set when the PME# signal is asserted independent of the state of the PME Enable bit

30	0h RW/1C	**SSE:** Reserved.
29	0h RW/1C	**Received Master Abort (RMA):** If the completion status received from IOSF is UR, Bridge sets this bit. S/W writes a 1. to this bit to clear it. This bit will not be set for the Fabric port. This bit is not used for the Fabric Port.
28	0h RW/1C	**Received Target Abort (RTA):** If the completion status received from IOSF is CA, Bridge sets this bit. S/W writes a 1.1 to this bit to clear it. This bit will not be set for the fabric port. This bit is not used for the Fabric Port.
27	0h RW/1C	**STA:** Reserved.
26:21	00h RO	**Reserved1:** Reserved.
20	1h RO	**Capabilities List (CAPLIST):** Hardwired to 1. Indicates that the controller contains a capabilities pointer list. The first item is pointed to by looking at configuration offset 34h. If PM capability is not required, then this bit should be tied to 0.
19	0h RO	**Interrupt Status (INTR_STATUS):** This bit reflects state of interrupt in the device. Only when the Interrupt Disable bit in the command register is a 0 and this Interrupt Status bit is a 1, will the device.s/function.s INTx# signal be asserted. Setting the Interrupt Disable bit to a 1 has no effect on the state of this bit. This bit reflects Legacy interrupt status.

Bit Range	Default & Access	Description
18:16	0h RO	**Reserved2:** Reserved.
15:11	00h RO	**Reserved3:** Reserved.
10	0h RW	**Interrupt Disable (INTR_DISABLE):** Setting this bit disables INTx assertion from Bridge. The interrupt disabled is legacy INTx# interrupt, i.e. Bridge does not send Interrupt Assert message through the IOSF SideBand Channel.
9	0h RO	**Reserved4:** Reserved.
8	0h RW	**SERR# Enable (SERR_ENABLE):** If both SERR# Enable and the Unsupported Request Reporting Enable(URRE) register are 1., the agent sets the Signaled System Error bit in the PCI Status Register and sends an ERR_NONFATAL message on the IOSF sideband interface.
7:3	00h RO	**Reserved5:** Reserved.
2	0h RW	**Bus Master Enable (BME):** If this bit is 0, Bridge does not generate any new upstream transaction on IOSF as a master.
1	0h RW	**Memory Space Enable (MSE):** This bit controls Bridge's response to downstream Memory accesses. When set, accesses to memory space of the device is enabled.
0	0h RO	**Reserved6:** Reserved.

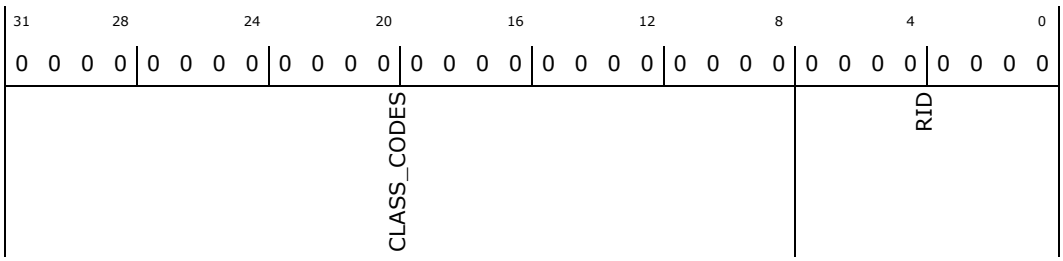
3.26.3 Revision ID and Class Code (REVCLASSCODE)—Offset 8h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

REVCLASSCODE: [B:0, D:30, F:0] + 8h

Default: 00000000h



Bit Range	Default & Access	Description
31:8	000000h RO	**Class Code (CLASS_CODES):** The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	**Revision ID (RID):** Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

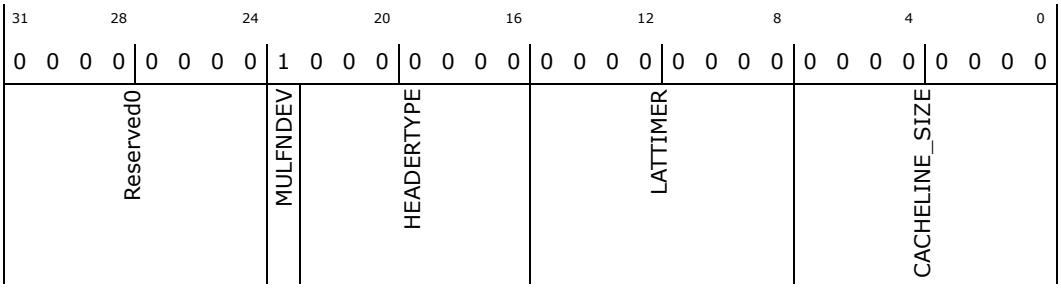
3.26.4 Cache Line Latency Header and BIST (CLLATHEADERBIST)—Offset Ch

Access Method

Type: PCI Configuration Register (Size: 32 bits)

CLLATHEADERBIST: [B:0, D:30, F:0] + Ch

Default: 00800000h



Bit Range	Default & Access	Description
31:24	00h RO	**Reserved0:** Reserved.
23	1h RO	**Multi Function Device (MULFNDEV):** This bit is always 0 for non fabric ports. For Fabric ports it is driven from fabric_mult_function strap. • 1 = multifunction device • 0 = single function device
22:16	00h RO	**Header Type (HEADERTYPE):** Implements Type 0 Configuration header.
15:8	00h RO	**Latency Timer (LATTIMER):** Does not apply to PCI Express. Hardwired to 00h.
7:0	00h RW	**Cache Line Size (CACHELINE_SIZE):** Doesn't apply to PCI Express. PCI Express spec requires this to be implemented as a R/W register but has no functional impact on the AHB Device connected.

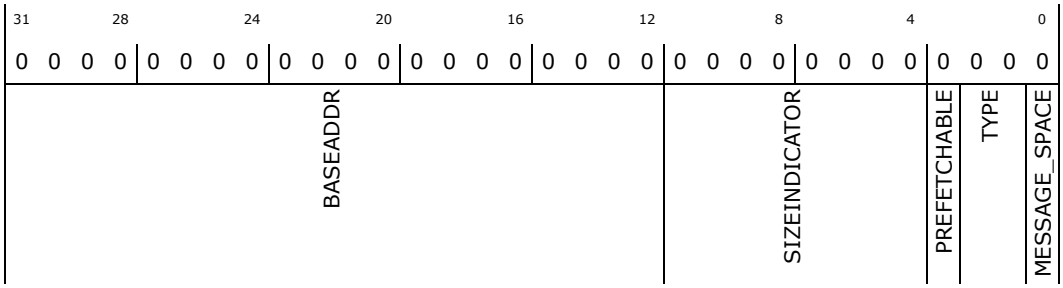
3.26.5 Base Address Register (BAR)—Offset 10h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

BAR: [B:0, D:30, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:12	00000h RW	**Base Address (BASEADDR):** Base address of the AHB device memory space. Taken from Strap values as 1.s
11:4	00h RO	**Size Indicator Read Only (SIZEINDICATOR):** Always returns zero. The size of this register depends on the size of the Memory space. This size is determined by a top level of STRAP values as 0.s. Always will be zero as minimum size is 4K.
3	0h RO	**Prefetchable (PREFETCHABLE):** Indicates that this BAR is not prefetchable.
2:1	0h RO	**Type (TYPE):** 00 indicates BAR lies in 32 bit address range.
0	0h RO	**Memory Space Indicator (MESSAGE_SPACE):** 0. Indicates this BAR is present in the memory space.

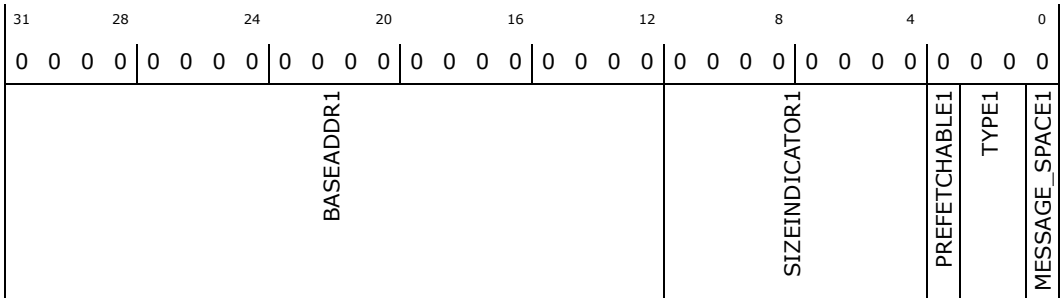
3.26.6 Base Address Register 1 (BAR1)—Offset 14h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

BAR1: [B:0, D:30, F:0] + 14h

Default: 00000000h



Bit Range	Default & Access	Description
31:12	00000h RW	**Base Address Register 1 (BASEADDR1):** BAR1 of the LPIO device.
11:4	00h RO	**SIZEINDICATOR1:** Always will be zero as minimum size is 4K.
3	0h RO	**Prefetchable (PREFETCHABLE1):** Indicates that this BAR is not.
2:1	0h RO	**Type (TYPE1):** 00 Indicates BAR lies in 32 bit address range.
0	0h RO	**Memory Space Indicator (MESSAGE_SPACE1):** 0. Indicates this BAR is present in the memory space.

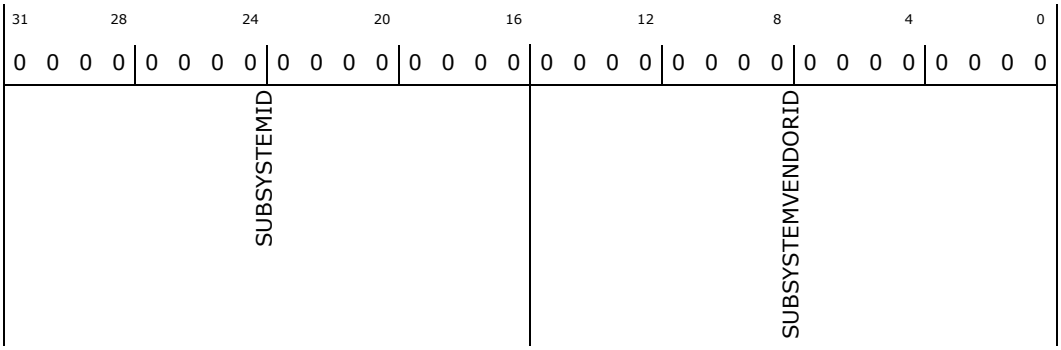
3.26.7 Subsystem Vendor and Subsystem ID (SUBSYSTEMID)—Offset 2Ch

Access Method

Type: PCI Configuration Register (Size: 32 bits)

SUBSYSTEMID: [B:0, D:30, F:0] + 2Ch

Default: 00000000h



Bit Range	Default & Access	Description
31:16	0000h RW/O	**Subsystem ID (SUBSYSTEMID):** This register should be implemented for any function that could be instantiated more than once in a given system. The SID register, in combination with the Subsystem Vendor ID register, make it possible for the operating environment to distinguish one audio subsystem from the other. This register is a Read Write Once type register.
15:0	0000h RW/O	**Subsystem Vendor ID (SUBSYSTEMVENDORID):** This register should be implemented for any function that could be instantiated more than once in a given system. The SVID register, in combination with the Subsystem ID register, enables the operating environment to distinguish one subsystem from the other. This register is a Read Write Once register.

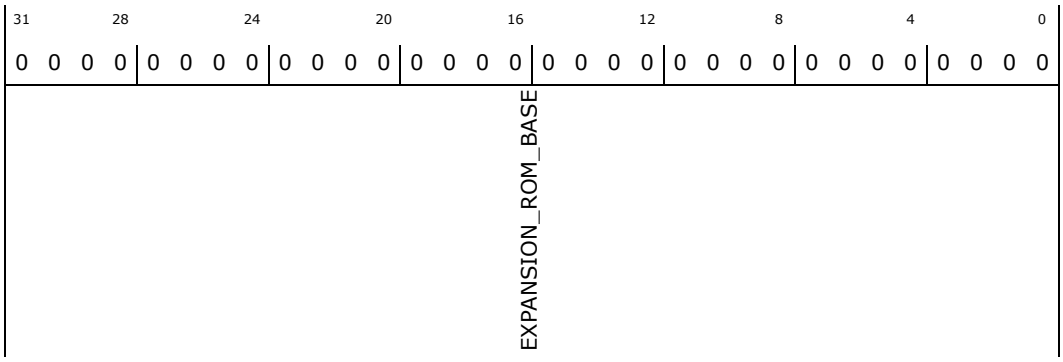
3.26.8 Expansion ROM Base Address (EXPANSION_ROM_BASEADDR)—Offset 30h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

EXPANSION_ROM_BASEADDR: [B:0, D:30, F:0] + 30h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	00000000h RO	**EXPANSION_ROM_BASE:** Reserved.

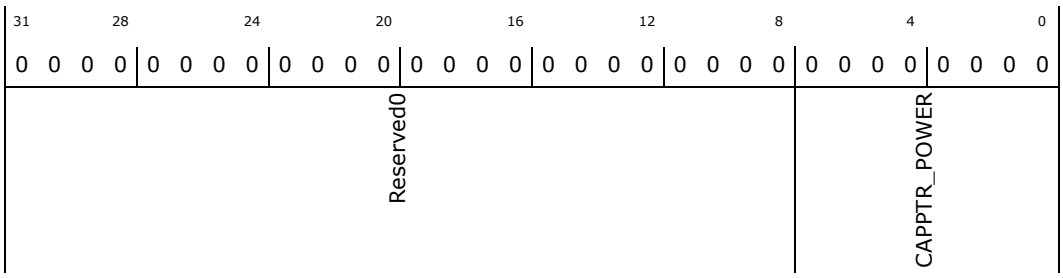
3.26.9 Capabilities Pointer (CAPABILITYPTR)—Offset 34h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

CAPABILITYPTR: [B:0, D:30, F:0] + 34h

Default: 00000000h



Bit Range	Default & Access	Description
31:8	000000h RO	**Reserved0:** Reserved.
7:0	00h RO	**Capabilities Pointer (CAPPTR_POWER):** Indicates what the next capability is. This capability can be programmed to be PM Capability (0x80) if PM Capability is enabled in SB. If PM capability is disabled then this register has 00h.

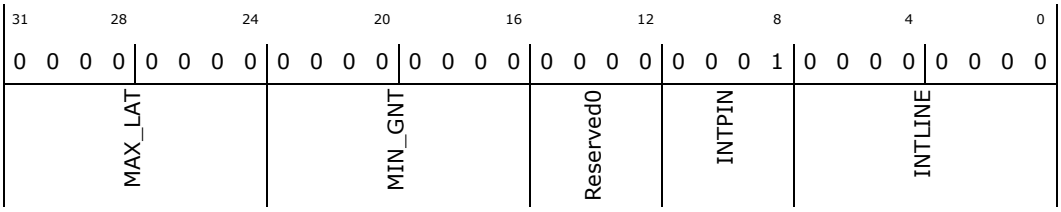
3.26.10 Interrupt Register (INTERRUPTREG)—Offset 3Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

INTERRUPTREG: [B:0, D:30, F:0] + 3Ch

Default: 00000100h



Bit Range	Default & Access	Description
31:24	00h RO	**Max_Lat (MAX_LAT):** Value of 0 indicates device has no major requirements for the settings of latency timers.
23:16	00h RO	**Min_Gnt (MIN_GNT):** Value of 0 indicates device has no major requirements for the settings of latency timers.
15:12	0h RO	**Reserved0:** Reserved.
11:8	1h RO	**Interrupt Pin (INTPIN):** Each AHB IP on Bridge is a Single function device. Hence Bridge only generates INTA on IOSF SB. The Fabric on AHB Bridge appears as a Multifunction device. Interrupt Pin Value in this register is reflected from the IPIN value in the private configuration space.
7:0	00h RW	**Interrupt Line (INTLINE):** Bridge does not use this field directly. It is used to tell software which interrupt line the interrupt pin is connected to.

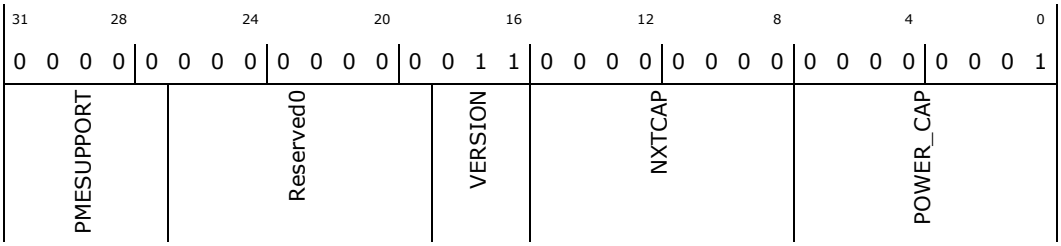
3.26.11 PowerManagement Capability ID (POWERCAPID)—Offset 80h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

POWERCAPID: [B:0, D:30, F:0] + 80h

Default: 00030001h



Bit Range	Default & Access	Description
31:27	00h RO	**PME_Support (PMESUPPORT):** This 5-bit field indicates the power states in which the function may assert PME#. A value of 0b for any bit indicates that the function is not capable of asserting the PME# signal while in that power state. • bit(11) X XXX1b - PME# can be asserted from D0. • bit(12) X XX1Xb - PME# can be asserted from D1. Bridge does not support this state. • bit(13) X X1XXb - PME# can be asserted from D2. Bridge does not support this state. • bit(14) X 1XXXb - PME# can be asserted from D3hot. • bit(15) 1 XXXXb - PME# can be asserted from D3cold. Bridge does not support this state. This field is taken from the strap strap_pme_support.
26:19	00h RO	**Reserved0:** Reserved.
18:16	3h RO	**Version (VERSION):** Indicates support for Revision 1.2 of the PCI Power Management Specification.
15:8	00h RO	**Next Capability (NXTCAP):** Points to the next capability structure. This points to NULL.
7:0	01h RO	**Power Management Capability (POWER_CAP):** Indicates this is power management capability.

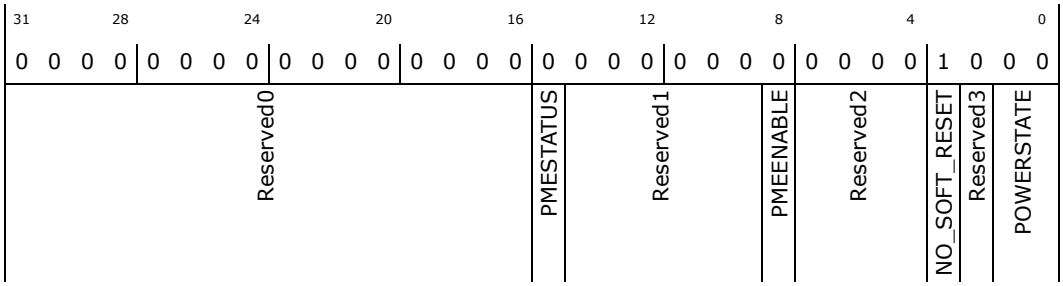
3.26.12 PME Control and Status Register (PMECTRLSTATUS)—Offset 84h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

PMECTRLSTATUS: [B:0, D:30, F:0] + 84h

Default: 00000008h



Bit Range	Default & Access	Description
31:16	0000h RO	**Reserved0:** Reserved.
15	0h RW/1C	**PME Status (PMESTATUS):** • 0 = Software clears the bit by writing a 1 to it. • 1 = This bit is set when the AHB Device would normally assert the PME# signal independent of the state of the PME Enable bit (bit 8 in this register).

Bit Range	Default & Access	Description
14:9	00h RO	**Reserved1:** Reserved.
8	0h RW	**PME Enable (PMEENABLE):** A 1 enables the function to assert PME#. When 0, PME# message on SB is disabled.
7:4	0h RO	**Reserved2:** Reserved.
3	1h RO	**No_Soft_Reset (NO_SOFT_RESET):** This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved.
2	0h RO	**Reserved3:** Reserved.
1:0	0h RW	**Power State (POWERSTATE):** This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: • 00 = D0 state • 11 = D3HOT state • Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, interrupts are blocked. D3Hot will not be used for Downstream decode on fabric ports.

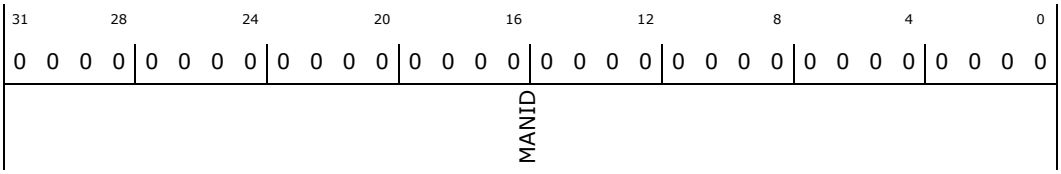
3.26.13 Manufacturer ID (MANID)—Offset F8h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

MANID: [B:0, D:30, F:0] + F8h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	00000000h RO	**Manufacturer ID (MANID):** This register is brought out as straps to the top level.

3.27.1 Source Address Register for Channel 0 - Low (SAR0_LO)—Offset 0h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current AHB transfer.

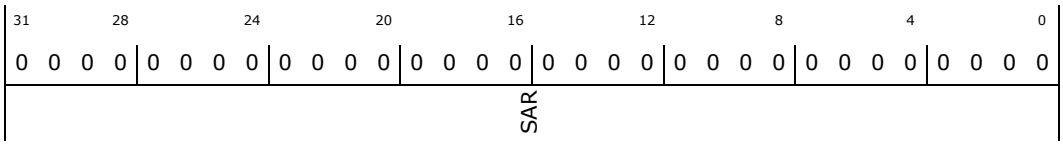
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR0_LO: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**Current Source Address of DMA Transfer (SAR):** Updated after each source transfer. The SINC field in the CTLx register determines whether the address increments, decrements, or is left unchanged on every source transfer throughout the block transfer.

3.27.2 Source Address Register for Channel 0 - High (SAR0_HI)—Offset 4h

Refer to the description for register Source Address Register for Channel 0 - Low.

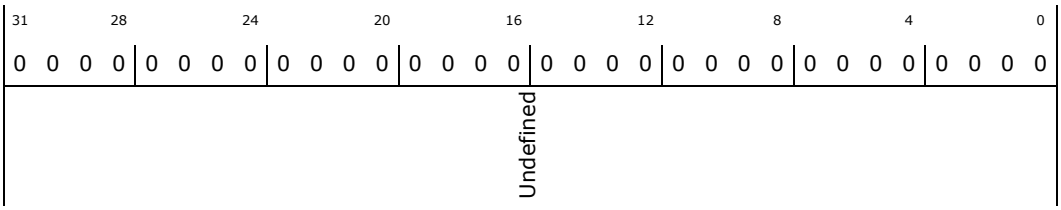
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR0_HI: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**Undefined:** RESERVED

3.27.3 Destination Address Register for Channel 0 - Low (DAR0_LO)—Offset 8h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current AHB transfer.

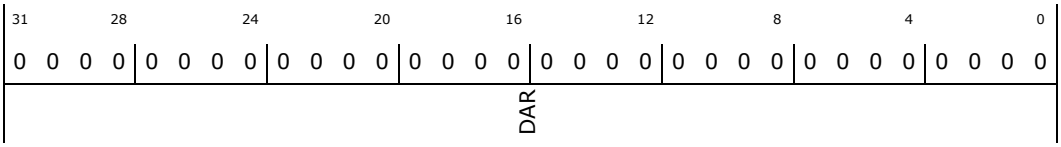
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

DAR0_LO: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**Current Destination Address of DMA Transfer (DAR):** Updated after each destination transfer. The DINC field in the CTLx register determines whether the address increments, decrements, or is left unchanged on every destination transfer throughout the block transfer.

3.27.4 Destination Address Register for Channel 0 - High (DAR0_HI)—Offset Ch

Refer to the description for register Destination Address Register for Channel 0 - Low.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

DAR0_HI: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

3.27.5 Linked List Pointer Register for Channel 0 - Low (LLP0_LO)—Offset 10h

This register does not exist if the DMAH_CHx_HC_LLP configuration parameter is set to True. For further details, refer to the DesignWare DW_ahb_dmac Databook.

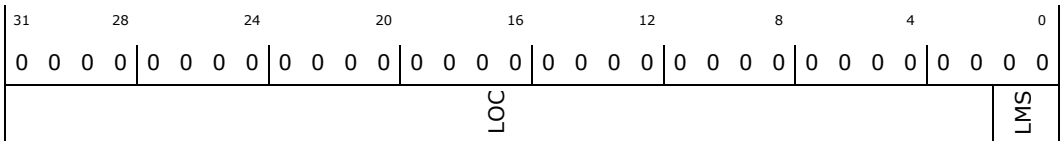
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

LLP0_LO: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:2	0h RW	**LOC:** Starting Address In Memory of next LLI if block chaining is enabled.
1:0	0h RW	**List Master Select (LMS):** Identifies the AHB layer/interface where the memory device that stores the next linked list item resides.

3.27.6 Linked List Pointer Register for Channel 0 - High (LLP0_HI)—Offset 14h

Refer to the description for register Linked List Pointer Register for Channel 0 - Low.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

LLP0_HI: [BAR] + 14h

BAR Type: PCI Configuration Register (Size: 32 bits)

16:14	1h RW	**Source Burst Transaction Length (SRC_MSIZE):** Number of data items, each of width CTLx.SRC_TR_WIDTH, to be read from the source every time a source burst transaction request is made from either the corresponding hardware or software handshaking interface. Refer to the DesignWare DW_ahb_dmac Databook for further details.
13:11	1h RW	**Destination Burst Transaction Length (DEST_MSIZE):** Number of data items, each of width CTLx.DST_TR_WIDTH, to be written to the destination every time a destination burst transaction request is made from either the corresponding hardware or software handshaking interface. Refer to the DesignWare DW_ahb_dmac Databook for further details.
10:9	0h RW	**Source Address Increment (SINC):** • 00 = Increment • 01 = Decrement • 1x = No change
8:7	0h RW	**Destination Address Increment (DINC):** Indicates whether to increment or decrement the destination address on every destination transfer. • 00 = Increment • 01 = Decrement • 1x = No change
6:4	0h RW	**Source Transfer Width (SRC_TR_WIDTH):** This value must be less than or equal to DMAH_Mx_HDATA_WIDTH, where x is the AHB layer 1 to 4 where the source resides.
3:1	0h RW	**Destination Transfer Width (DST_TR_WIDTH):** This value must be less than or equal to DMAH_Mk_HDATA_WIDTH, where k is the AHB layer 1 to 4 where the destination resides.

Bit Range	Default & Access	Description
0	1h RW	**Interrupt Enable Bit (INT_EN):** If set, then all interrupt-generating sources are enabled.

3.27.8 Control Register for Channel 0 - High (CTL0_HI)—Offset 1Ch

Refer to the register description for Control Register for Channel 0 - Low.

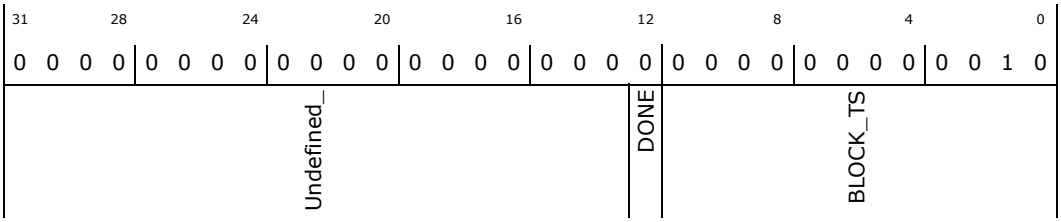
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL0_HI: [BAR] + 1Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000002h



Bit Range	Default & Access	Description
31:13	0h RW	**Undefined_:** RESERVED
12	0h RW	**Done Bit (DONE):** If status write-back is enabled, the upper word of the control register, CTLx[63:32], is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTLx.DONE bit to see when a block transfer is complete. The LLI CTLx.DONE bit should be cleared when the linked lists are set up in memory, prior to enabling the channel. LLI accesses are always 32-bit accesses (Hsize = 2) aligned to 32-bit boundaries and cannot be changed or programmed to anything other than 32-bit. For more information, refer to the DesignWare DW_ahb_dmac Databook.
11:0	2h RW	**Block Transfer Size (BLOCK_TS):** When the DW_ahb_dmac is the flow controller, the user writes this field before the channel is enabled in order to indicate the block size.

3.27.9 Source Status Register for Channel 0 - Low (SSTAT0_LO)—Offset 20h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Refer to the DesignWare DW_ahb_dmac Databook for further details.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SSTAT0_LO: [BAR] + 20h

3.27.11 Dest Status Register for Channel 0 - Low (DSTAT0_LO)—Offset 28h

After the completion of each block transfer, hardware can retrieve the destination status information from the address pointed to by the contents of the DSTATARx register. This status information is then stored in the DSTATx register and written out to the DSTATx register location of the LLI (refer to the DesignWare DW_ahb_dmac Databook for further details) before the start of the next block. For conditions under which the destination status information is fetched, refer to the abovementioned spec.

3.27.17 Configuration Register for Channel 0 - Low (CFG0_LO)—Offset 40h

This register contains fields that configure the DMA transfer. The channel configuration register remains fixed for all blocks of a multi-block transfer.

Note: You need to program this register prior to enabling the channel.

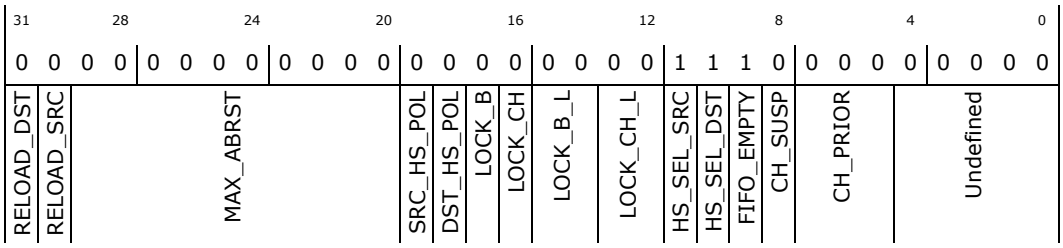
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CFG0_LO: [BAR] + 40h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000E00h



Bit Range	Default & Access	Description
31	0h RW	**Automatic Destination Reload (RELOAD_DST):** The DARx register can be automatically reloaded from its initial value at the end of every block for multi-block transfers.
30	0h RW	**Automatic Source Reload (RELOAD_SRC):** The SARx register can be automatically reloaded from its initial value at the end of every block for multi-block transfers.
29:20	0h RW	**Maximum AMBA Burst Length (MAX_ABRST):** Maximum AMBA burst length that is used for DMA transfers on this channel. A value of 0 indicates that software is not limiting the maximum AMBA burst length for DMA transfers on this channel.

Bit Range	Default & Access	Description
19	0h RW	**Source Handshaking Interface Polarity (SRC_HS_POL):** • 0 = Active high • 1 = Active low
18	0h RW	**Destination Handshaking Interface Polarity (DST_HS_POL):** • 0 = Active high • 1 = Active low
17	0h RW	**Bus Lock Bit (LOCK_B):** When active, the AHB bus master signal hlock is asserted for the duration specified in CFGx.LOCK_B_L.
16	0h RW	**Channel Lock Bit (LOCK_CH):** When the channel is granted control of the master bus interface and if the CFGx.LOCK_CH bit is asserted, then no other channels are granted control of the master bus interface for the duration specified in CFGx.LOCK_CH_L. Indicates to the master bus interface arbiter that this channel wants exclusive access to the master bus interface for the duration specified in CFGx.LOCK_CH_L.
15:14	0h RW	**Bus Lock Level (LOCK_B_L):** Indicates the duration over which CFGx.LOCK_B bit applies. • 00 = Over complete DMA transfer • 01 = Over complete DMA block transfer • 1x = Over complete DMA transaction
13:12	0h RW	**Channel Lock Level (LOCK_CH_L):** Indicates the duration over which CFGx.LOCK_CH bit applies. • 00 = DMA transfer • 01 = DMA block transfer • 1x = DMA transaction
11	1h RW	**Source Software or Hardware Handshaking Select (HS_SEL_SRC):** • 0 = HW handshaking • 1 = SW handshaking
10	1h RW	**Destination Software or Hardware Handshaking Select (HS_SEL_DST):** • 0 = HW handshaking • 1 = SW handshaking
9	1h RO	**FIFO_EMPTY:** Indicates whether there is data left in the channel FIFO.
8	0h RW	**Channel Suspend (CH_SUSP):** Suspends all DMA transfers from source until this bit is cleared.
7:5	0h RW	**Channel Priority (CH_PRIOR):** Priority of 7 is the highest priority.

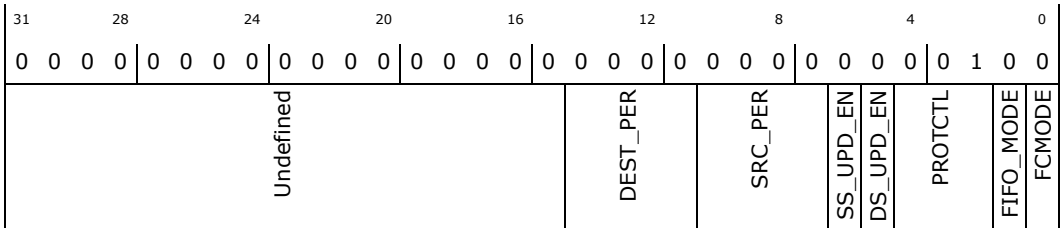
CFG0_HI: [BAR] + 44h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000004h



Bit Range	Default & Access	Description
31:15	0h RW	**Undefined:** Reserved.
14:11	0h RW	**DEST_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the destination of channel x if the CFGx.HS_SEL_DST field is 0; otherwise, this field is ignored.
10:7	0h RW	**SRC_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the source of channel x if the CFGx.HS_SEL_SRC field is 0; otherwise, this field is ignored.
6	0h RW	**Source Status Update Enable (SS_UPD_EN):** Source status information is fetched only from the location pointed to by the SSTATARx register, stored in the SSTATx register and written out to the SSTATx location of the LLI (refer to Figure 52 on page 243) if SS_UPD_EN is high.
5	0h RW	**Destination Status Update Enable (DS_UPD_EN):** Destination status information is fetched only from the location pointed to by the DSTATARx register, stored in the DSTATx register and written out to the DSTATx location of the LLI if DS_UPD_EN is high.
4:2	1h RW	**PROTCTL:** Protection Control bits used to drive the AHB HPROT[3:1] bus.
1	0h RW	**FIFO Mode Select (FIFO_MODE):** Determines how much space or data needs to be available in the FIFO before a burst transaction request is serviced. • 0 = Space/data available for single AHB transfer of the specified transfer width. • 1 = Data available is greater than or equal to half the FIFO depth for destination transfers and space available is greater than half the fifo depth for source transfers.
0	0h RW	**Flow Control Mode (FCMODE):** Determines when source transaction requests are serviced when the Destination Peripheral is the flow controller. • 0 = Source transaction requests are serviced when they occur. Data pre-fetching is enabled. • 1 = Source transaction requests are not serviced until a destination transaction request occurs.

3.27.19 Source Gather Register for Channel 0 - Low (SGR0_LO)—Offset 48h

The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored. This register does not exist if the configuration parameter DMAH_CHx_SRC_GAT_EN is set to False. For more information, refer to the DesignWare DW_ahb_dmac Databook.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SGR0_LO: [BAR] + 48h

BAR Type: PCI Configuration Register (Size: 32 bits)

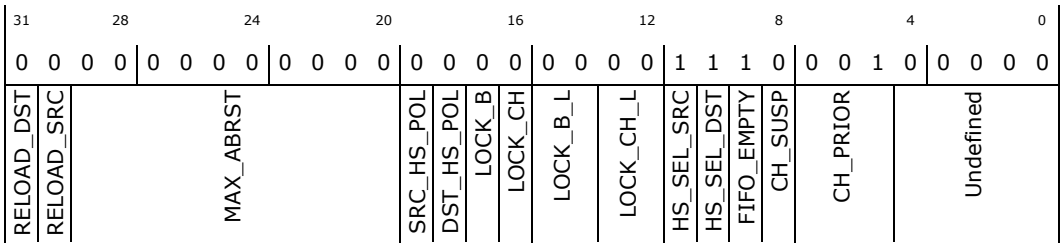
CFG1_LO: [BAR] + 98h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000E20h



Bit Range	Default & Access	Description
31	0h RW	**Automatic Destination Reload (RELOAD_DST):** The DARx register can be automatically reloaded from its initial value at the end of every block for multi-block transfers.
30	0h RW	**Automatic Source Reload (RELOAD_SRC):** The SARx register can be automatically reloaded from its initial value at the end of every block for multi-block transfers.

Bit Range	Default & Access	Description
29:20	0h RW	**Maximum AMBA Burst Length (MAX_ABRST):** Maximum AMBA burst length that is used for DMA transfers on this channel. A value of 0 indicates that software is not limiting the maximum AMBA burst length for DMA transfers on this channel.
19	0h RW	**Source Handshaking Interface Polarity (SRC_HS_POL):** • 0 = Active high • 1 = Active low
18	0h RW	**Destination Handshaking Interface Polarity (DST_HS_POL):** • 0 = Active high • 1 = Active low
17	0h RW	**Bus Lock Bit (LOCK_B):** When active, the AHB bus master signal hlock is asserted for the duration specified in CFGx.LOCK_B_L.
16	0h RW	**Channel Lock Bit (LOCK_CH):** When the channel is granted control of the master bus interface and if the CFGx.LOCK_CH bit is asserted, then no other channels are granted control of the master bus interface for the duration specified in CFGx.LOCK_CH_L. Indicates to the master bus interface arbiter that this channel wants exclusive access to the master bus interface for the duration specified in CFGx.LOCK_CH_L.
15:14	0h RW	**Bus Lock Level (LOCK_B_L):** Indicates the duration over which CFGx.LOCK_B bit applies. • 00 = Over complete DMA transfer • 01 = Over complete DMA block transfer • 1x = Over complete DMA transaction
13:12	0h RW	**Channel Lock Level (LOCK_CH_L):** Indicates the duration over which CFGx.LOCK_CH bit applies. 00 = DMA transfer 01 = DMA block transfer 1x = DMA transaction
11	1h RW	**Source Software or Hardware Handshaking Select (HS_SEL_SRC):** • 0 = HW handshaking • 1 = SW handshaking
10	1h RW	**Destination Software or Hardware Handshaking Select (HS_SEL_DST):** • 0 = HW handshaking • 1 = SW handshaking
9	1h RO	**FIFO_EMPTY:** Indicates whether there is data left in the channel FIFO.
8	0h RW	**Channel Suspend (CH_SUSP):** Suspends all DMA transfers from source until this bit is cleared.
7:5	1h RW	**Channel Priority (CH_PRIOR):** Priority of 7 is the highest priority.
4:0	0h RW	**Undefined:** RESERVED

3.27.40 Configuration Register for Channel 1 - High (CFG1_HI)—Offset 9Ch

Refer to the register description for Configuration Register for Channel 0 - Low.

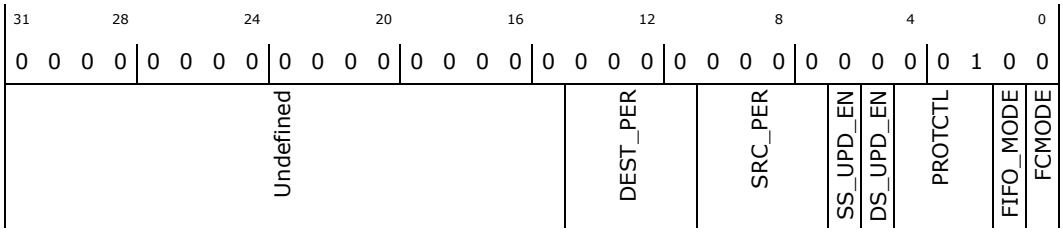
CFG1_HI: [BAR] + 9Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000004h



Bit Range	Default & Access	Description
31:15	0h RW	**Undefined:** Reserved.
14:11	0h RW	**DEST_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the destination of channel x if the CFGx.HS_SEL_DST field is 0; otherwise, this field is ignored.
10:7	0h RW	**SRC_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the source of channel x if the CFGx.HS_SEL_SRC field is 0; otherwise, this field is ignored.
6	0h RW	**Source Status Update Enable (SS_UPD_EN):** Source status information is fetched only from the location pointed to by the SSTATARx register, stored in the SSTATx register and written out to the SSTATx location of the LLI (refer to Figure 52 on page 243) if SS_UPD_EN is high.
5	0h RW	**Destination Status Update Enable (DS_UPD_EN):** Destination status information is fetched only from the location pointed to by the DSTATARx register, stored in the DSTATx register and written out to the DSTATx location of the LLI if DS_UPD_EN is high.
4:2	1h RW	**PROTCTL:** Protection Control bits used to drive the AHB HPROT[3:1] bus.
1	0h RW	**FIFO Mode Select (FIFO_MODE):** Determines how much space or data needs to be available in the FIFO before a burst transaction request is serviced. • 0 = Space/data available for single AHB transfer of the specified transfer width. • 1 = Data available is greater than or equal to half the FIFO depth for destination transfers and space available is greater than half the fifo depth for source transfers.
0	0h RW	**Flow Control Mode (FCMODE):** Determines when source transaction requests are serviced when the Destination Peripheral is the flow controller. • 0 = Source transaction requests are serviced when they occur. Data pre-fetching is enabled. • 1 = Source transaction requests are not serviced until a destination transaction request occurs.

3.27.41 Source Gather Register for Channel 1 - Low (SGR1_LO)—Offset A0h

3.27.61 Configuration Register for Channel 2 - Low (CFG2_LO)—Offset F0h

Refer to the register description for Configuration Register for Channel 0 - Low.

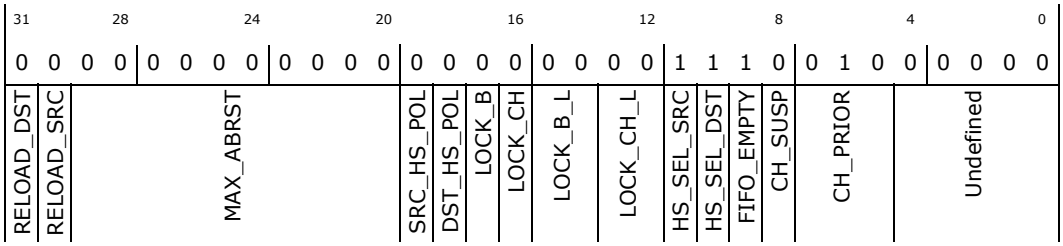
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CFG2_LO: [BAR] + F0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000E40h



Bit Range	Default & Access	Description
31	0h RW	**Automatic Destination Reload (RELOAD_DST):** The DARx register can be automatically reloaded from its initial value at the end of every block for multi-block transfers.
30	0h RW	**Automatic Source Reload (RELOAD_SRC):** The SARx register can be automatically reloaded from its initial value at the end of every block for multi-block transfers.
29:20	0h RW	**Maximum AMBA Burst Length (MAX_ABRST):** Maximum AMBA burst length that is used for DMA transfers on this channel. A value of 0 indicates that software is not limiting the maximum AMBA burst length for DMA transfers on this channel.
19	0h RW	**Source Handshaking Interface Polarity (SRC_HS_POL):** • 0 = Active high • 1 = Active low
18	0h RW	**Destination Handshaking Interface Polarity (DST_HS_POL):** • 0 = Active high • 1 = Active low
17	0h RW	**Bus Lock Bit (LOCK_B):** When active, the AHB bus master signal hlock is asserted for the duration specified in CFGx.LOCK_B_L.
16	0h RW	**Channel Lock Bit (LOCK_CH):** When the channel is granted control of the master bus interface and if the CFGx.LOCK_CH bit is asserted, then no other channels are granted control of the master bus interface for the duration specified in CFGx.LOCK_CH_L. Indicates to the master bus interface arbiter that this channel wants exclusive access to the master bus interface for the duration specified in CFGx.LOCK_CH_L.

Bit Range	Default & Access	Description
15:14	0h RW	**Bus Lock Level (LOCK_B_L):** Indicates the duration over which CFGx.LOCK_B bit applies. • 00 = Over complete DMA transfer • 01 = Over complete DMA block transfer • 1x = Over complete DMA transaction
13:12	0h RW	**Channel Lock Level (LOCK_CH_L):** Indicates the duration over which CFGx.LOCK_CH bit applies. • 00 = DMA transfer • 01 = DMA block transfer • 1x = DMA transaction
11	1h RW	**Source Software or Hardware Handshaking Select (HS_SEL_SRC):** • 0 = HW handshaking • 1 = SW handshaking
10	1h RW	**Destination Software or Hardware Handshaking Select (HS_SEL_DST):** • 0 = HW handshaking • 1 = SW handshaking
9	1h RO	**FIFO_EMPTY:** Indicates if there is data left in the channel FIFO.
8	0h RW	**Channel Suspend (CH_SUSP):** Suspends all DMA transfers from source until this bit is cleared.
7:5	2h RW	**Channel Priority (CH_PRIOR):** Priority of 7 is the highest priority.
4:0	0h RW	**Undefined:** RESERVED

3.27.62 Configuration Register for Channel 2 - High (CFG2_HI)—Offset F4h

Refer to the register description for Configuration Register for Channel 0 - Low.

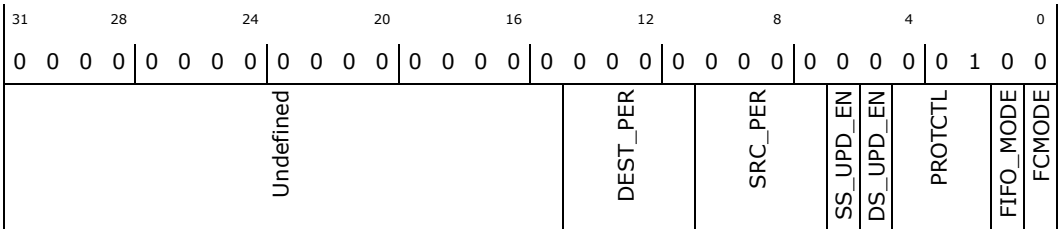
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CFG2_HI: [BAR] + F4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000004h



Bit Range	Default & Access	Description
31:15	0h RW	**Undefined:** Reserved.
14:11	0h RW	**DEST_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the destination of channel x if the CFGx.HS_SEL_DST field is 0; otherwise, this field is ignored.
10:7	0h RW	**SRC_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the source of channel x if the CFGx.HS_SEL_SRC field is 0; otherwise, this field is ignored.
6	0h RW	**Source Status Update Enable (SS_UPD_EN):** Source status information is fetched only from the location pointed to by the SSTATARx register, stored in the SSTATx register and written out to the SSTATx location of the LLI (refer to Figure 52 on page 243) if SS_UPD_EN is high.
5	0h RW	**Destination Status Update Enable (DS_UPD_EN):** Destination status information is fetched only from the location pointed to by the DSTATARx register, stored in the DSTATx register and written out to the DSTATx location of the LLI if DS_UPD_EN is high.
4:2	1h RW	**PROTCTL:** Protection Control bits used to drive the AHB HPROT[3:1] bus.
1	0h RW	**FIFO Mode Select (FIFO_MODE):** Determines how much space or data needs to be available in the FIFO before a burst transaction request is serviced. • 0 = Space/data available for single AHB transfer of the specified transfer width. • 1 = Data available is greater than or equal to half the FIFO depth for destination transfers and space available is greater than half the fifo depth for source transfers.
0	0h RW	**Flow Control Mode (FCMODE):** Determines when source transaction requests are serviced when the Destination Peripheral is the flow controller. • 0 = Source transaction requests are serviced when they occur. Data pre-fetching is enabled. • 1 = Source transaction requests are not serviced until a destination transaction request occurs.

3.27.63 Source Gather Register for Channel 2 - Low (SGR2_LO)—Offset F8h

Refer to the register description for Source Gather Register for Channel 0 - Low.

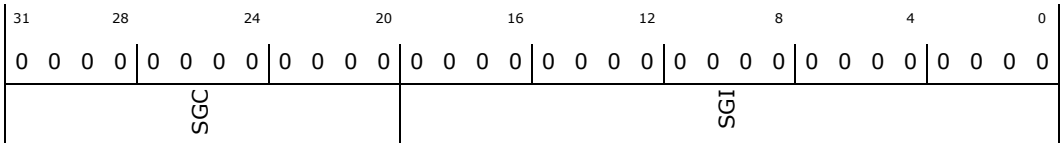
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SGR2_LO: [BAR] + F8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:20	0h RW	**Source Gather Count (SGC):** Source contiguous transfer count between successive gather boundaries. Refer to the DesignWare DW_ahb_dmac Databook for further details.
19:0	0h RW	**Source Gather Interval (SGI):** Refer to the description for SGR0_LO.SGI.

3.27.64 Source Gather Register for Channel 2 - High (SGR2_HI)—Offset FCh

Refer to the register description for Source Gather Register for Channel 0 - Low.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SGR2_HI: [BAR] + FCh

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

31:0	0h RW	**Undefined:** Reserved.

3.27.67 Source Address Register for Channel 3 - Low (SAR3_LO)—Offset 108h

Refer to the description for register Source Address Register for Channel 0 - Low.

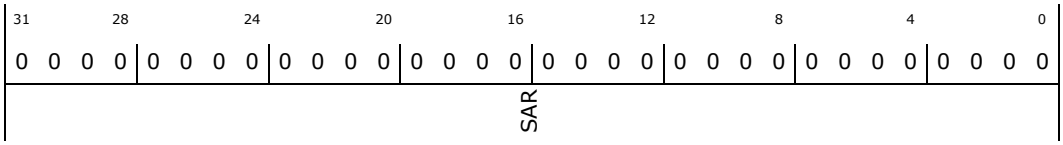
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR3_LO: [BAR] + 108h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**Current Source Address of DMA Transfer (SAR):** Updated after each source transfer. The SINC field in the CTLx register determines whether the address increments, decrements, or is left unchanged on every source transfer throughout the block transfer.

3.27.68 Source Address Register for Channel 3 - High (SAR3_HI)—Offset 10Ch

Refer to the description for register Source Address Register for Channel 0 - Low.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR3_HI: [BAR] + 10Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

3.27.69 Destination Address Register for Channel 3 - Low (DAR3_LO)—Offset 110h

Refer to the description for register Destination Address Register for Channel 0 - Low.

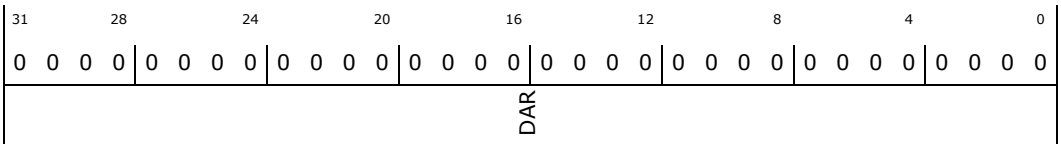
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

DAR3_LO: [BAR] + 110h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**Current Destination Address of DMA Transfer (DAR):** Updated after each destination transfer. The DINC field in the CTLx register determines whether the address increments, decrements, or is left unchanged on every destination transfer throughout the block transfer.

3.27.70 Destination Address Register for Channel 3 - High (DAR3_HI)—Offset 114h

Refer to the description for register Destination Address Register for Channel 0 - Low.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

DAR3_HI: [BAR] + 114h

BAR Type: PCI Configuration Register (Size: 32 bits)

31:0	0h RW	**Undefined:** Reserved.

3.27.71 Linked List Pointer Register for Channel 3 - Low (LLP3_LO)—Offset 118h

Refer to the description for register Linked List Pointer Register for Channel 0 - Low.

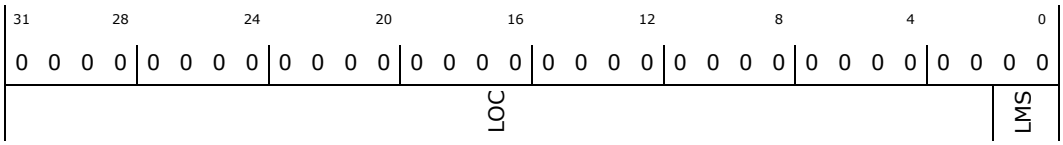
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

LLP3_LO: [BAR] + 118h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:2	0h RW	**LOC:** Starting Address In Memory of next LLI if block chaining is enabled.
1:0	0h RW	**List Master Select (LMS):** Identifies the AHB layer/interface where the memory device that stores the next linked list item resides.

3.27.72 Linked List Pointer Register for Channel 3 - High (LLP3_HI)—Offset 11Ch

Refer to the description for register Linked List Pointer Register for Channel 0 - Low.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

LLP3_HI: [BAR] + 11Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

16:14	1h RW	**Source Burst Transaction Length (SRC_MSIZE):** Refer to the description of CTL0_LO.SRC_MSIZE.
13:11	1h RW	**Destination Burst Transaction Length (DEST_MSIZE):** Refer to the description for CTL0_LO.DEST_MSIZE.
10:9	0h RW	**Source Address Increment (SINC):** • 00 = Increment • 01 = Decrement • 1x = No change
8:7	0h RW	**Destination Address Increment (DINC):** Indicates whether to increment or decrement the destination address on every destination transfer. • 00 = Increment • 01 = Decrement • 1x = No change
6:4	0h RW	**Source Transfer Width (SRC_TR_WIDTH):** This value must be less than or equal to DMAH_Mx_HDATA_WIDTH, where x is the AHB layer 1 to 4 where the source resides.

Bit Range	Default & Access	Description
3:1	0h RW	**Destination Transfer Width (DST_TR_WIDTH):** This value must be less than or equal to DMAH_Mk_HDATA_WIDTH, where k is the AHB layer 1 to 4 where the destination resides.
0	1h RW	**Interrupt Enable Bit (INT_EN):** If set, then all interrupt-generating sources are enabled.

3.27.74 Control Register for Channel 3 - High (CTL3_HI)—Offset 124h

Refer to the register description for Control Register for Channel 0 - Low.

Access Method

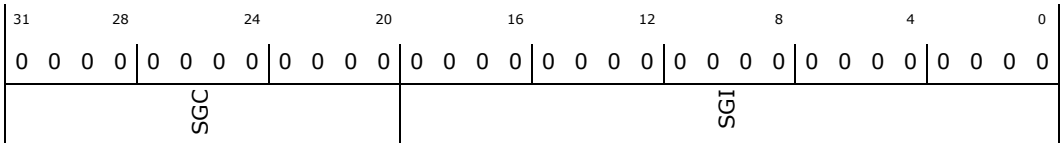
SGR3_LO: [BAR] + 150h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:20	0h RW	**Source Gather Count (SGC):** Source contiguous transfer count between successive gather boundaries. Refer to the DesignWare DW_ahb_dmac Databook for further details.
19:0	0h RW	**Source Gather Interval (SGI):** Refer to the description for SGR0_LO.SGI.

3.27.86 Source Gather Register for Channel 3 - High (SGR3_HI)—Offset 154h

Refer to the register description for Source Gather Register for Channel 0 - Low.

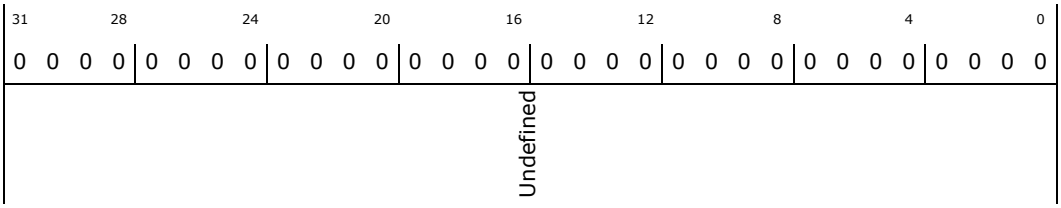
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SGR3_HI: [BAR] + 154h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**Undefined:** Reserved.

3.27.87 Destination Scatter Register for Channel 3 - Low (DSR3_LO)—Offset 158h

Refer to the register description for Destination Scatter Register for Channel 0 - Low.

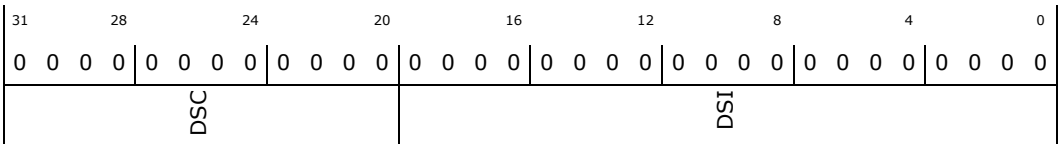
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

DSR3_LO: [BAR] + 158h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:20	0h RW	**Dest Scatter Count (DSC):** Destination contiguous transfer count between successive scatter boundaries.
19:0	0h RW	**Dest Scatter Interval (DSI):** Refer to the description for DSR0_LO.DSI.

3.27.88 Dest Scatter Register for Channel 3 - High (DSR3_HI)—Offset 15Ch

Refer to the register description for Destination Scatter Register for Channel 0 - Low.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

DSR3_HI: [BAR] + 15Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

31:0	0h RW	**Undefined:** Reserved.

3.27.89 Source Address Register for Channel 4 - Low (SAR4_LO)—Offset 160h

Refer to the description for register Source Address Register for Channel 0 - Low.

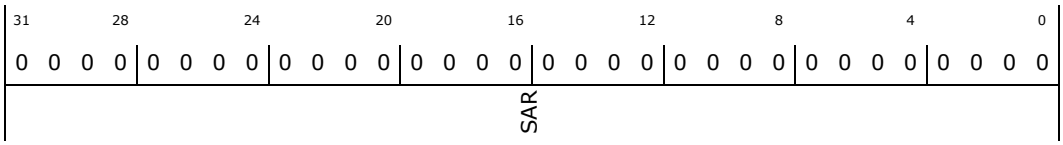
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR4_LO: [BAR] + 160h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**SAR:** Current Source Address of DMA transfer. Updated after each source transfer. The SINC field in the CTLx register determines whether the address increments, decrements, or is left unchanged on every source transfer throughout the block transfer.

3.27.90 Source Address Register for Channel 4 - High (SAR4_HI)—Offset 164h

Refer to the description for register Source Address Register for Channel 0 - Low.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR4_HI: [BAR] + 164h

BAR Type: PCI Configuration Register (Size: 32 bits)

Bit Range	Default & Access	Description
31:29	0h RW	**Undefined_:** RESERVED
28	0h RW	**LLP_SRC_EN:** Block chaining is enabled on the source side only if the LLP_SRC_EN field is high and LLPx.LOC is non-zero
27	0h RW	**LLP_DST_EN:** Block chaining is enabled on the destination side only if the LLP_DST_EN field is high and LLPx.LOC is non-zero.

Bit Range	Default & Access	Description
26:25	0h RW	**Source Master Select (SMS):** Identifies the Master Interface layer from which the source device (peripheral or memory) is accessed.
24:23	0h RW	**Destination Master Select (DMS):** Identifies the Master Interface layer where the destination device (peripheral or memory) resides.
22:20	3h RW	**Transfer Type and Flow Control (TT_FC):** Refer to description for CTL0_LO.TT_FC.
19	0h RW	**Undefined:** RESERVED
18	0h RW	**Destination Scatter Enable Bit (DST_SCATTER_EN):** • 0 = disabled • 1 = enabled
17	0h RW	**Source Gather Enable Bit (SRC_GATHER_EN):** • 0 = disabled • 1 = enabled
16:14	1h RW	**Source Burst Transaction Length (SRC_MSIZE):** Refer to the description of CTL0_LO.SRC_MSIZE.
13:11	1h RW	**Destination Burst Transaction Length (DEST_MSIZE):** Refer to the description for CTL0_LO.DEST_MSIZE.
10:9	0h RW	**Source Address Increment (SINC):** • 00 = Increment • 01 = Decrement • 1x = No change
8:7	0h RW	**Destination Address Increment (DINC):** Indicates whether to increment or decrement the destination address on every destination transfer. • 00 = Increment • 01 = Decrement • 1x = No change
6:4	0h RW	**Source Transfer Width (SRC_TR_WIDTH):** This value must be less than or equal to DMAH_Mx_HDATA_WIDTH, where x is the AHB layer 1 to 4 where the source resides.
3:1	0h RW	**Destination Transfer Width (DST_TR_WIDTH):** This value must be less than or equal to DMAH_Mk_HDATA_WIDTH, where k is the AHB layer 1 to 4 where the destination resides.
0	1h RW	**Interrupt Enable Bit (INT_EN):** If set, then all interrupt-generating sources are enabled.

3.27.96 Control Register for Channel 4 - High (CTL4_HI)—Offset 17Ch

Refer to the register description for Control Register for Channel 0 - Low.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL4_HI: [BAR] + 17Ch

BAR Type: PCI Configuration Register (Size: 32 bits)

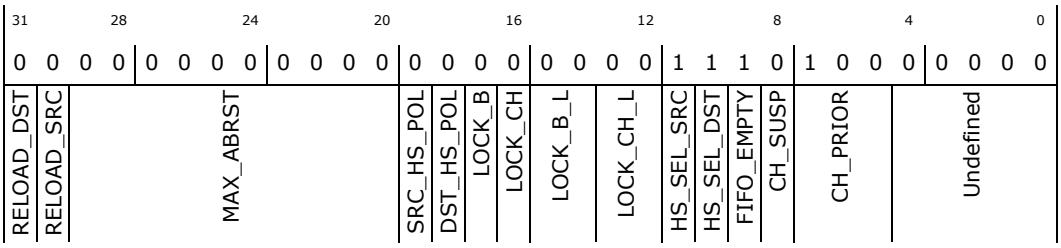
CFG4_LO: [BAR] + 1A0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000E80h



Bit Range	Default & Access	Description
31	0h RW	**Automatic Destination Reload (RELOAD_DST):** The DARx register can be automatically reloaded from its initial value at the end of every block for multi-block transfers.
30	0h RW	**Automatic Source Reload (RELOAD_SRC):** The SARx register can be automatically reloaded from its initial value at the end of every block for multi-block transfers.

Bit Range	Default & Access	Description
29:20	0h RW	**Maximum AMBA Burst Length (MAX_ABRST):** Maximum AMBA burst length that is used for DMA transfers on this channel. A value of 0 indicates that software is not limiting the maximum AMBA burst length for DMA transfers on this channel.
19	0h RW	**Source Handshaking Interface Polarity (SRC_HS_POL):** • 0 = Active high • 1 = Active low
18	0h RW	**Destination Handshaking Interface Polarity (DST_HS_POL):** • 0 = Active high • 1 = Active low
17	0h RW	**Bus Lock Bit (LOCK_B):** When active, the AHB bus master signal hlock is asserted for the duration specified in CFGx.LOCK_B_L.
16	0h RW	**Channel Lock Bit (LOCK_CH):** When the channel is granted control of the master bus interface and if the CFGx.LOCK_CH bit is asserted, then no other channels are granted control of the master bus interface for the duration specified in CFGx.LOCK_CH_L. Indicates to the master bus interface arbiter that this channel wants exclusive access to the master bus interface for the duration specified in CFGx.LOCK_CH_L.
15:14	0h RW	**Bus Lock Level (LOCK_B_L):** Indicates the duration over which CFGx.LOCK_B bit applies. • 00 = Over complete DMA transfer • 01 = Over complete DMA block transfer • 1x = Over complete DMA transaction
13:12	0h RW	**Channel Lock Level (LOCK_CH_L):** Indicates the duration over which CFGx.LOCK_CH bit applies. • 00 = DMA transfer • 01 = DMA block transfer • 1x = DMA transaction
11	1h RW	**Source Software or Hardware Handshaking Select (HS_SEL_SRC):** • 0 = HW handshaking • 1 = SW handshaking
10	1h RW	**Destination Software or Hardware Handshaking Select (HS_SEL_DST):** • 0 = HW handshaking • 1 = SW handshaking
9	1h RO	**FIFO_EMPTY:** Indicates if there is data left in the channel FIFO.
8	0h RW	**Channel Suspend (CH_SUSP):** Suspends all DMA transfers from source until this bit is cleared.
7:5	4h RW	**Channel Priority (CH_PRIOR):** Priority of 7 is the highest priority.
4:0	0h RW	**Undefined:** RESERVED

3.27.106 Configuration Register for Channel 4 - High (CFG4_HI)—Offset 1A4h

Refer to the register description for Configuration Register for Channel 0 - Low.

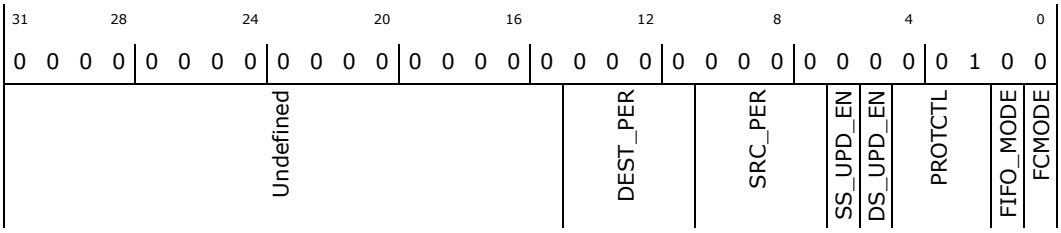
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CFG4_HI: [BAR] + 1A4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000004h



Bit Range	Default & Access	Description
31:15	0h RW	**Undefined:** Reserved.
14:11	0h RW	**DEST_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the destination of channel x if the CFGx.HS_SEL_DST field is 0; otherwise, this field is ignored.
10:7	0h RW	**SRC_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the source of channel x if the CFGx.HS_SEL_SRC field is 0; otherwise, this field is ignored.
6	0h RW	**Source Status Update Enable (SS_UPD_EN):** Source status information is fetched only from the location pointed to by the SSTATARx register, stored in the SSTATx register and written out to the SSTATx location of the LLI (refer to Figure 52 on page 243) if SS_UPD_EN is high.
5	0h RW	**Destination Status Update Enable (DS_UPD_EN):** Destination status information is fetched only from the location pointed to by the DSTATARx register, stored in the DSTATx register and written out to the DSTATx location of the LLI if DS_UPD_EN is high.
4:2	1h RW	**PROTCTL:** Protection Control bits used to drive the AHB HPROT[3:1] bus.
1	0h RW	**FIFO Mode Select (FIFO_MODE):** Determines how much space or data needs to be available in the FIFO before a burst transaction request is serviced. • 0 = Space/data available for single AHB transfer of the specified transfer width. • 1 = Data available is greater than or equal to half the FIFO depth for destination transfers and space available is greater than half the fifo depth for source transfers.
0	0h RW	**Flow Control Mode (FCMODE):** Determines when source transaction requests are serviced when the Destination Peripheral is the flow controller. • 0 = Source transaction requests are serviced when they occur. Data pre-fetching is enabled. • 1 = Source transaction requests are not serviced until a destination transaction request occurs.

3.27.107 Source Gather Register for Channel 4 - Low (SGR4_LO)—Offset 1A8h

Refer to the register description for Source Gather Register for Channel 0 - Low.

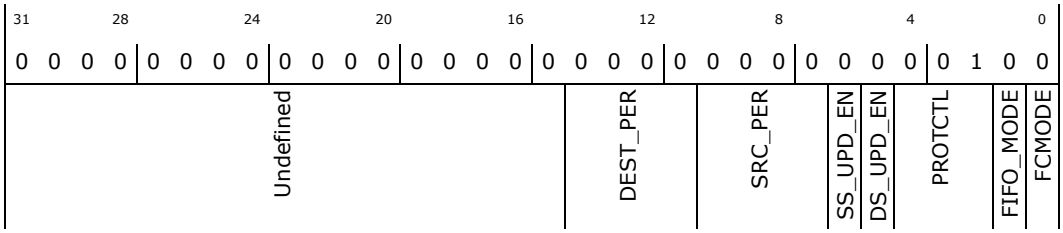
Default: 00000004h



Bit Range	Default & Access	Description
31:15	0h RW	**Undefined:** Reserved.
14:11	0h RW	**DEST_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the destination of channel x if the CFGx.HS_SEL_DST field is 0; otherwise, this field is ignored.
10:7	0h RW	**SRC_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the source of channel x if the CFGx.HS_SEL_SRC field is 0; otherwise, this field is ignored.
6	0h RW	**Source Status Update Enable (SS_UPD_EN):** Source status information is fetched only from the location pointed to by the SSTATARx register, stored in the SSTATx register and written out to the SSTATx location of the LLI (refer to Figure 52 on page 243) if SS_UPD_EN is high.
5	0h RW	**Destination Status Update Enable (DS_UPD_EN):** Destination status information is fetched only from the location pointed to by the DSTATARx register, stored in the DSTATx register and written out to the DSTATx location of the LLI if DS_UPD_EN is high.
4:2	1h RW	**PROTCTL:** Protection Control bits used to drive the AHB HPROT[3:1] bus.
1	0h RW	**FIFO Mode Select (FIFO_MODE):** Determines how much space or data needs to be available in the FIFO before a burst transaction request is serviced. • 0 = Space/data available for single AHB transfer of the specified transfer width. • 1 = Data available is greater than or equal to half the FIFO depth for destination transfers and space available is greater than half the FIFO depth for source transfers.
0	0h RW	**Flow Control Mode (FCMODE):** Determines when source transaction requests are serviced when the Destination Peripheral is the flow controller. • 0 = Source transaction requests are serviced when they occur. Data pre-fetching is enabled. • 1 = Source transaction requests are not serviced until a destination transaction request occurs.

3.27.177 Interrupt Raw Status Registers - Low (RawTfr_LO)—Offset 2C0h

Interrupt events are stored in these Raw Interrupt Status registers before masking: RawBlock, RawDstTran, RawErr, RawSrcTran, and RawTfr. Each Raw Interrupt Status register has a bit allocated per channel; for example, RawTfr[2] is the Channel 2 raw transfer complete interrupt.

Each bit in these registers is cleared by writing a 1 to the corresponding location in the ClearTfr, ClearBlock, ClearSrcTran, ClearDstTran, ClearErr registers.

3.27.218 Combined Interrupt Status Register - High (StatusInt_HI)—Offset 364h

Refer to the description for register StatusInt_LO.

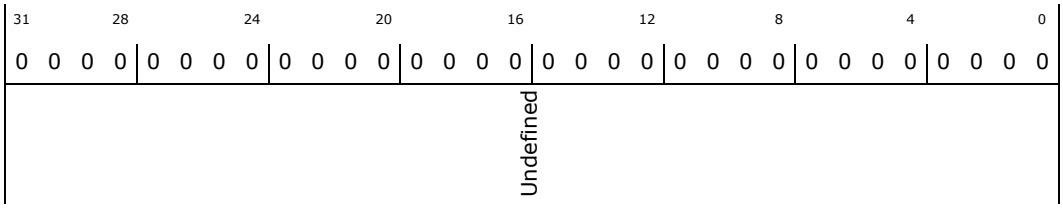
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

StatusInt_HI: [BAR] + 364h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**Undefined:** Reserved.

3.27.219 Source Software Transaction Request Register - Low (ReqSrcReg_LO)—Offset 368h

A bit is assigned for each channel in this register. ReqSrcReg[n] is ignored when software handshaking is not enabled for the source of channel n.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

ReqSrcReg_LO: [BAR] + 368h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

3.27.233 DW_ahb_dmac Channel Enable Register - Low (ChEnReg_LO)—Offset 3A0h

This is the DW_ahb_dmac Channel Enable Register. If software needs to set up a new channel, then it can read this register in order to find out which channels are currently inactive; it can then enable an inactive channel with the required priority.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

ChEnReg_LO: [BAR] + 3A0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:30, F:0] + 10h

3.27.237 DW_ahb_dmac Test Register - Low (DmaTestReg_LO)—Offset 3B0h

This register is used to put the AHB slave interface into test mode, during which the readback value of the writable registers match the value written, assuming the DW_ahb_dmac configuration has not optimized the same registers. In normal operation, the readback value of some registers is a function of the DW_ahb_dmac state, and does not match the value written.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

DmaTestReg_LO: [BAR] + 3B0h

BAR Type: PCI Configuration Register (Size: 32 bits)

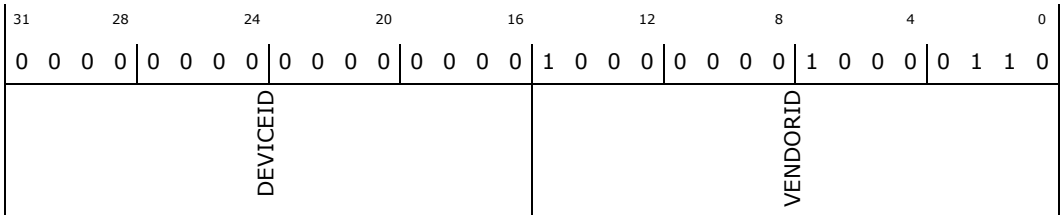
3.28.1 Device ID and Vendor ID Register (DEVVENDID)—Offset 0h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

DEVVENDID: [B:0, D:24, F:0] + 0h

Default: 00008086h



Bit Range	Default & Access	Description
31:16	0000h RO	**Device ID (DEVICEID):** Device ID identifies the particular AHB device. This is tied to a strap at the top level.

Bit Range	Default & Access	Description
15:0	8086h RO	**Vendor ID (VENDORID):** Vendor ID is a unique ID provided by PCI SIG which identifies the manufacturer of the device. This is tied to a strap at the top level.

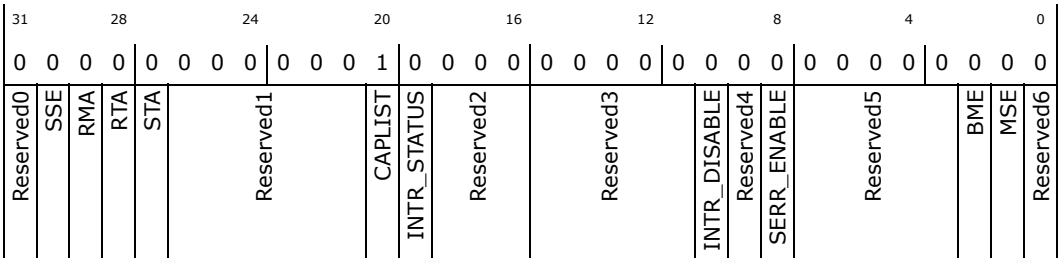
3.28.2 Status and Command (STATUSCOMMAND)—Offset 4h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

STATUSCOMMAND: [B:0, D:24, F:0] + 4h

Default: 00100000h



Bit Range	Default & Access	Description
31	0h RO	**Reserved0:** Reserved.
30	0h RW/1C	**SSE:** Reserved.
29	0h RW/1C	**Received Master Abort (RMA):** If the completion status received from IOSF is UR, Bridge sets this bit. S/W writes a 1. to this bit to clear it. This bit will not be set for the Fabric port. This bit is not used for the Fabric Port.
28	0h RW/1C	**Received Target Abort (RTA):** If the completion status received from IOSF is CA, Bridge sets this bit. S/W writes a 1.1 to this bit to clear it. This bit will not be set for the fabric port. This bit is not used for the Fabric Port.
27	0h RW/1C	**STA:** Reserved.
26:21	00h RO	**Reserved1:** Reserved.
20	1h RO	**Capabilities List (CAPLIST):** Hardwired to 1. Indicates that the controller contains a capabilities pointer list. The first item is pointed to by looking at configuration offset 34h. If PM capability is not required, then this bit should be tied to 0.
19	0h RO	**Interrupt Status (INTR_STATUS):** This bit reflects state of interrupt in the device. Only when the Interrupt Disable bit in the command register is a 0 and this Interrupt Status bit is a 1, will the device.s/function.s INTx# signal be asserted. Setting the Interrupt Disable bit to a 1 has no effect on the state of this bit. This bit reflects Legacy interrupt status.
18:16	0h RO	**Reserved2:** Reserved.

Bit Range	Default & Access	Description
15:11	00h RO	**Reserved3:** Reserved.
10	0h RW	**Interrupt Disable (INTR_DISABLE):** Setting this bit disables INTx assertion from Bridge. The interrupt disabled is legacy INTx# interrupt, i.e. Bridge does not send Interrupt Assert message through the IOSF SideBand Channel.
9	0h RO	**Reserved4:** Reserved.
8	0h RW	**SERR# Enable (SERR_ENABLE):** If both SERR# Enable and the Unsupported Request Reporting Enable(URRE) register are 1., the agent sets the Signaled System Error bit in the PCI Status Register and sends an ERR_NONFATAL message on the IOSF sideband interface.
7:3	00h RO	**Reserved5:** Reserved.
2	0h RW	**Bus Master Enable (BME):** If this bit is 0, Bridge does not generate any new upstream transaction on IOSF as a master.
1	0h RW	**Memory Space Enable (MSE):** This bit controls Bridge's response to downstream Memory accesses. When set, accesses to memory space of the device is enabled.
0	0h RO	**Reserved6:** Reserved.

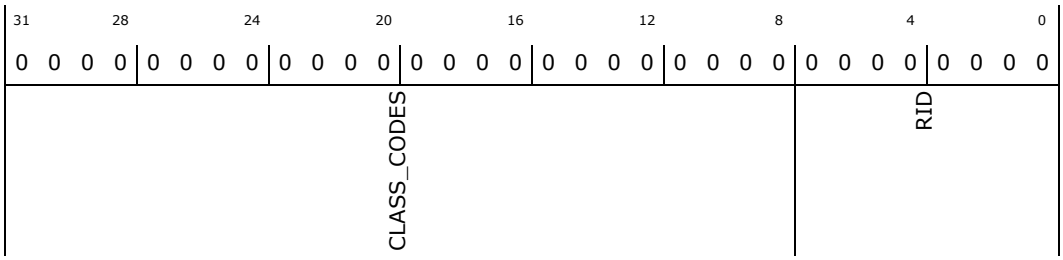
3.28.3 Revision ID and Class Code (REVCLASSCODE)—Offset 8h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

REVCLASSCODE: [B:0, D:24, F:0] + 8h

Default: 00000000h



Bit Range	Default & Access	Description
31:8	000000h RO	**Class Code (CLASS_CODES):** The Class Code register is read-only and used to identify the generic function of the device and, in some cases, a specific register level programming interface. The register is broken into three byte size fields. The upper byte (at offset 0Bh) is a base class code which broadly classifies the type of function the device performs. The middle byte (at offset 0Ah) is a sub-class code which identifies more specifically the function of the device. The lower byte (at offset 09h) identifies a specific register-level programming interface (if any) so that device independent software can interact with the device. This register is tied to a strap at the top level.
7:0	00h RO	**Revision ID (RID):** Revision ID identifies the revision of particular AHB device. This is tied to a strap at the top level.

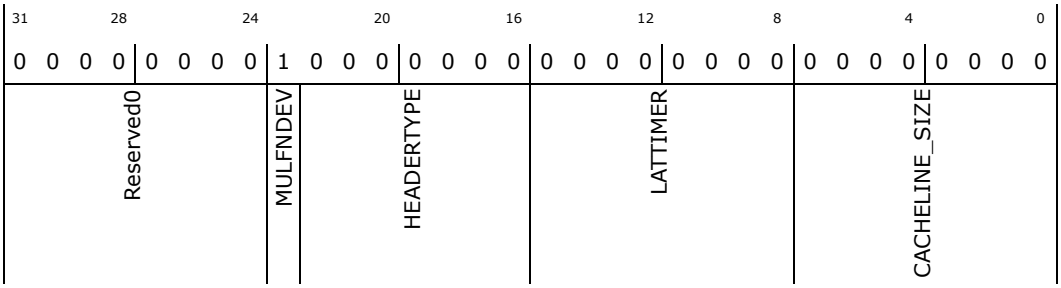
3.28.4 Cache Line Latency Header and BIST (CLLATHEADERBIST)—Offset Ch

Access Method

Type: PCI Configuration Register (Size: 32 bits)

CLLATHEADERBIST: [B:0, D:24, F:0] + Ch

Default: 00800000h



Bit Range	Default & Access	Description
31:24	00h RO	**Reserved0:** Reserved.
23	1h RO	**Multi Function Device (MULFNDEV):** This bit is always 0 for non fabric ports. For Fabric ports it is driven from fabric_mult_function strap. • 1 = multifunction device • 0 = single function device
22:16	00h RO	**Header Type (HEADERTYPE):** Implements Type 0 Configuration header.
15:8	00h RO	**Latency Timer (LATTIMER):** Does not apply to PCI Express. Hardwired to 00h.
7:0	00h RW	**Cache Line Size (CACHELINE_SIZE):** Doesn't apply to PCI Express. PCI Express spec requires this to be implemented as a R/W register but has no functional impact on the AHB Device connected.

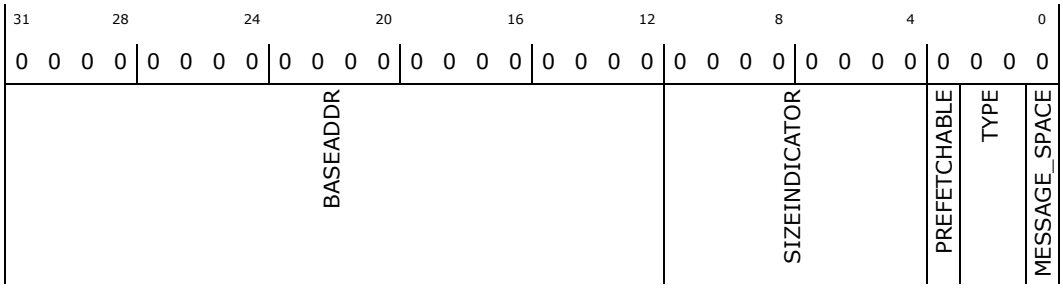
3.28.5 Base Address Register (BAR)—Offset 10h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

BAR: [B:0, D:24, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:12	00000h RW	**Base Address (BASEADDR):** Base address of the AHB device memory space. Taken from Strap values as 1.s
11:4	00h RO	**Size Indicator Read Only (SIZEINDICATOR):** Always returns zero. The size of this register depends on the size of the Memory space. This size is determined by a top level of STRAP values as 0.s. Always will be zero as minimum size is 4K.
3	0h RO	**Prefetchable (PREFETCHABLE):** Indicates that this BAR is not prefetchable.
2:1	0h RO	**Type (TYPE):** 00 indicates BAR lies in 32 bit address range.
0	0h RO	**Memory Space Indicator (MESSAGE_SPACE):** 0. Indicates this BAR is present in the memory space.

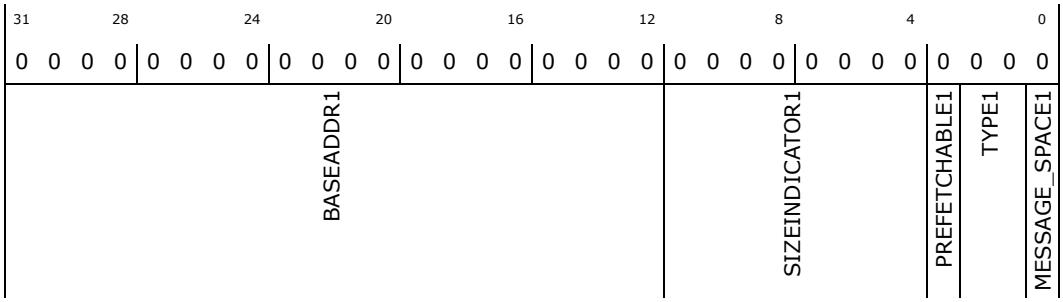
3.28.6 Base Address Register 1 (BAR1)—Offset 14h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

BAR1: [B:0, D:24, F:0] + 14h

Default: 00000000h



Bit Range	Default & Access	Description
31:12	00000h RW	**Base Address Register 1 (BASEADDR1):** BAR1 of the LPIO device.
11:4	00h RO	**SIZEINDICATOR1:** Always will be zero as minimum size is 4K.
3	0h RO	**Prefetchable (PREFETCHABLE1):** Indicates that this BAR is not.
2:1	0h RO	**Type (TYPE1):** 00 Indicates BAR lies in 32 bit address range.
0	0h RO	**Memory Space Indicator (MESSAGE_SPACE1):** 0. Indicates this BAR is present in the memory space.

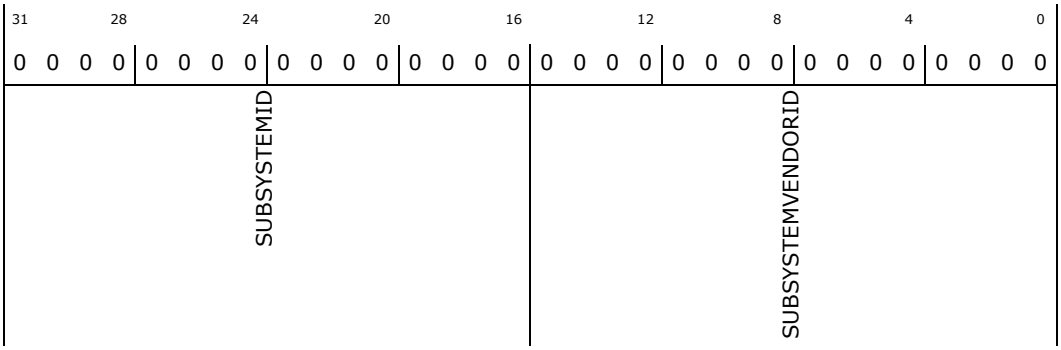
3.28.7 Subsystem Vendor and Subsystem ID (SUBSYSTEMID)—Offset 2Ch

Access Method

Type: PCI Configuration Register (Size: 32 bits)

SUBSYSTEMID: [B:0, D:24, F:0] + 2Ch

Default: 00000000h



Bit Range	Default & Access	Description
31:16	0000h RW/O	**Subsystem ID (SUBSYSTEMID):** This register should be implemented for any function that could be instantiated more than once in a given system. The SID register, in combination with the Subsystem Vendor ID register, make it possible for the operating environment to distinguish one audio subsystem from the other. This register is a Read Write Once type register.
15:0	0000h RW/O	**Subsystem Vendor ID (SUBSYSTEMVENDORID):** This register should be implemented for any function that could be instantiated more than once in a given system. The SVID register, in combination with the Subsystem ID register, enables the operating environment to distinguish one subsystem from the other. This register is a Read Write Once register.

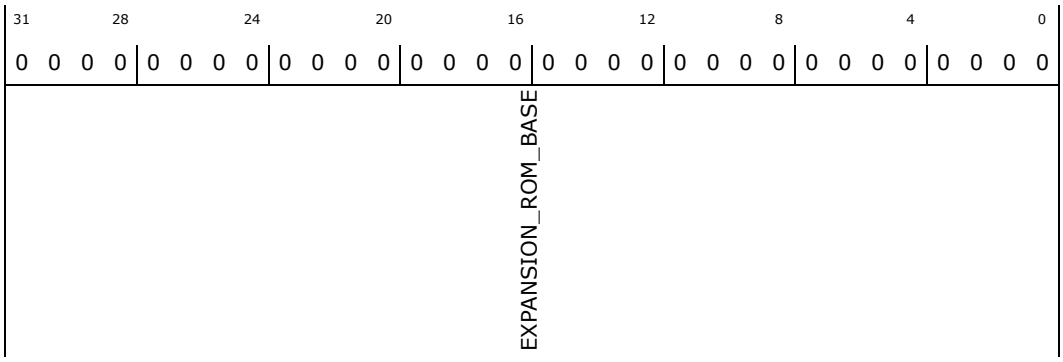
3.28.8 Expansion ROM Base Address (EXPANSION_ROM_BASEADDR)—Offset 30h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

EXPANSION_ROM_BASEADDR: [B:0, D:24, F:0] + 30h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	00000000h RO	**EXPANSION_ROM_BASE:** Reserved.

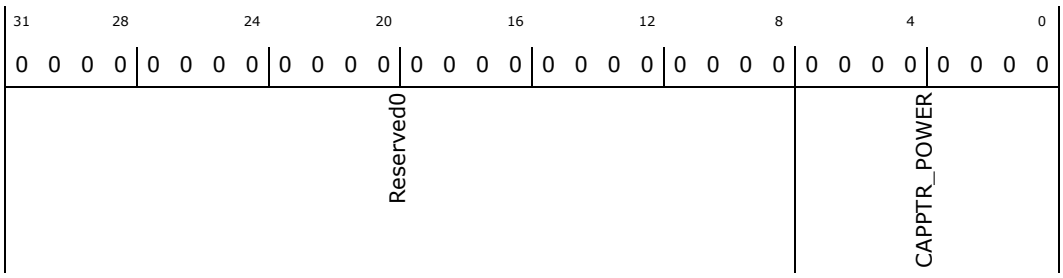
3.28.9 Capabilities Pointer (CAPABILITYPTR)—Offset 34h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

CAPABILITYPTR: [B:0, D:24, F:0] + 34h

Default: 00000000h



Bit Range	Default & Access	Description
31:8	000000h RO	**Reserved0:** Reserved.
7:0	00h RO	**Capabilities Pointer (CAPPTR_POWER):** Indicates what the next capability is. This capability can be programmed to be PM Capability (0x80) if PM Capability is enabled in SB. If PM capability is disabled then this register has 00h.

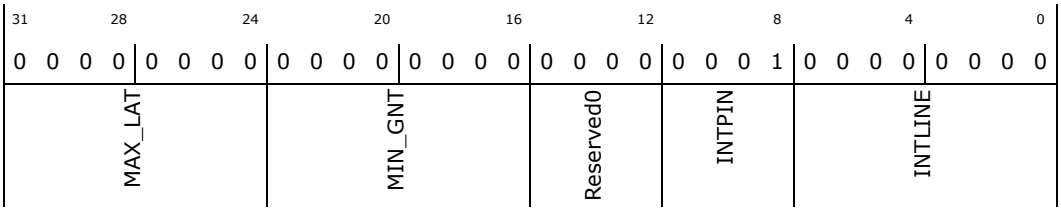
3.28.10 Interrupt Register (INTERRUPTREG)—Offset 3Ch

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

INTERRUPTREG: [B:0, D:24, F:0] + 3Ch

Default: 00000100h



Bit Range	Default & Access	Description
31:24	00h RO	**Max_Lat (MAX_LAT):** Value of 0 indicates device has no major requirements for the settings of latency timers.
23:16	00h RO	**Min_Gnt (MIN_GNT):** Value of 0 indicates device has no major requirements for the settings of latency timers.
15:12	0h RO	**Reserved0:** Reserved.
11:8	1h RO	**Interrupt Pin (INTPIN):** Each AHB IP on Bridge is a Single function device. Hence Bridge only generates INTA on IOSF SB. The Fabric on AHB Bridge appears as a Multifunction device. Interrupt Pin Value in this register is reflected from the IPIN value in the private configuration space.
7:0	00h RW	**Interrupt Line (INTLINE):** Bridge does not use this field directly. It is used to tell software which interrupt line the interrupt pin is connected to.

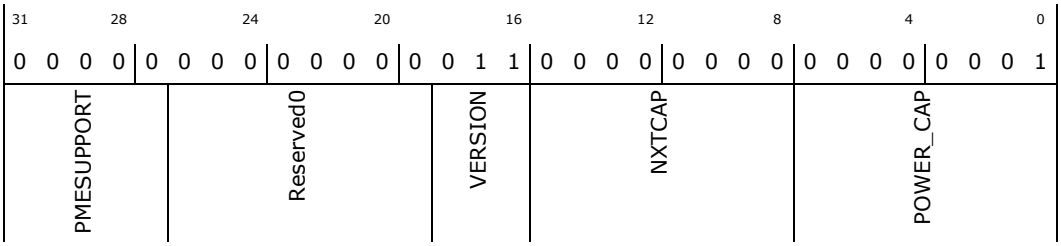
3.28.11 PowerManagement Capability ID (POWERCAPID)—Offset 80h

Access Method

Type: PCI Configuration Register
(Size: 32 bits)

POWERCAPID: [B:0, D:24, F:0] + 80h

Default: 00030001h



Bit Range	Default & Access	Description
31:27	00h RO	**PME_Support (PMESUPPORT):** This 5-bit field indicates the power states in which the function may assert PME#. A value of 0b for any bit indicates that the function is not capable of asserting the PME# signal while in that power state. • bit(11) X XXX1b - PME# can be asserted from D0. • bit(12) X XX1Xb - PME# can be asserted from D1. Bridge does not support this state. • bit(13) X X1XXb - PME# can be asserted from D2. Bridge does not support this state. • bit(14) X 1XXXb - PME# can be asserted from D3hot. • bit(15) 1 XXXXb - PME# can be asserted from D3cold. Bridge does not support this state. This field is taken from the strap strap_pme_support.
26:19	00h RO	**Reserved0:** Reserved.
18:16	3h RO	**Version (VERSION):** Indicates support for Revision 1.2 of the PCI Power Management Specification.
15:8	00h RO	**Next Capability (NXTCAP):** Points to the next capability structure. This points to NULL.
7:0	01h RO	**Power Management Capability (POWER_CAP):** Indicates this is power management capability.

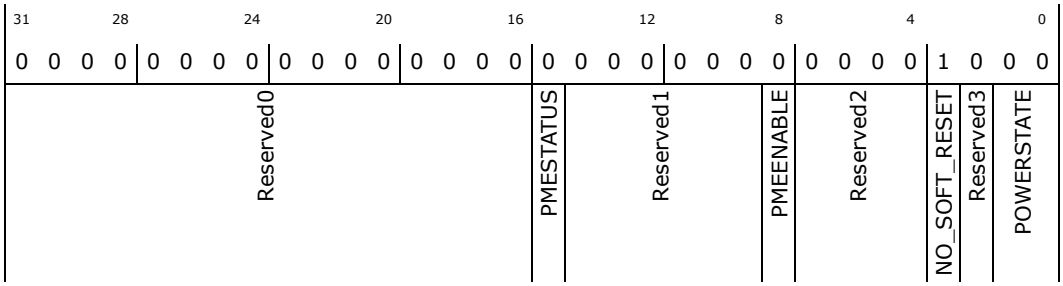
3.28.12 PME Control and Status Register (PMECTRLSTATUS)—Offset 84h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

PMECTRLSTATUS: [B:0, D:24, F:0] + 84h

Default: 00000008h



Bit Range	Default & Access	Description
31:16	0000h RO	**Reserved0:** Reserved.
15	0h RW/1C	**PME Status (PMESTATUS):** • 0 = Software clears the bit by writing a 1 to it. • 1 = This bit is set when the AHB Device would normally assert the PME# signal independent of the state of the PME Enable bit (bit 8 in this register).

Bit Range	Default & Access	Description
14:9	00h RO	**Reserved1:** Reserved.
8	0h RW	**PME Enable (PMEENABLE):** A 1 enables the function to assert PME#. When 0, PME# message on SB is disabled.
7:4	0h RO	**Reserved2:** Reserved.
3	1h RO	**No_Soft_Reset (NO_SOFT_RESET):** This bit indicates that devices transitioning from D3hot to D0 because of PowerState commands do not perform an internal reset. Configuration Context is preserved.
2	0h RO	**Reserved3:** Reserved.
1:0	0h RW	**Power State (POWERSTATE):** This field is used both to determine the current power state of the AHB IP and to set a new power state. The values are: • 00 = D0 state • 11 = D3HOT state • Others = Reserved Notes: If software attempts to write a value of 01b or 10b in to this field, the write operation must complete normally; however, the data is discarded and no state change occurs. When in the D3HOT states, interrupts are blocked. D3Hot will not be used for Downstream decode on fabric ports.

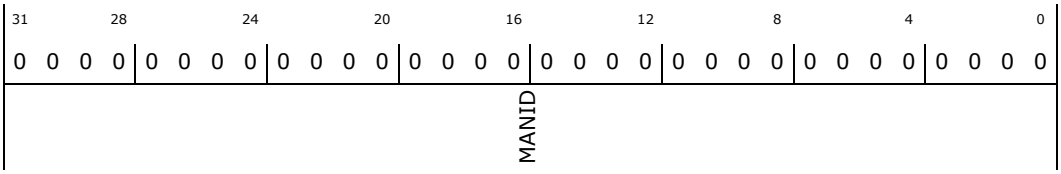
3.28.13 Manufacturer ID (MANID)—Offset F8h

Access Method

Type: PCI Configuration Register (Size: 32 bits)

MANID: [B:0, D:24, F:0] + F8h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	00000000h RO	**Manufacturer ID (MANID):** This register is brought out as straps to the top level.

3.29.1 Source Address Register for Channel 0 - Low (SAR0_LO)—Offset 0h

The starting source address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the source address of the current AHB transfer.

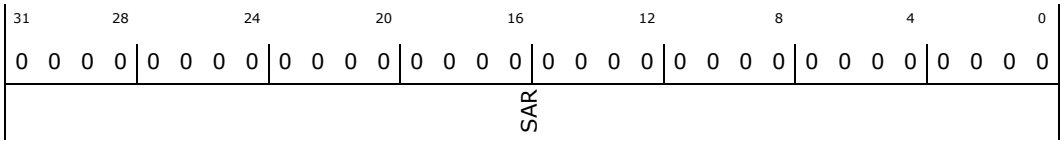
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR0_LO: [BAR] + 0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**Current Source Address of DMA Transfer (SAR):** Updated after each source transfer. The SINC field in the CTLx register determines whether the address increments, decrements, or is left unchanged on every source transfer throughout the block transfer.

3.29.2 Source Address Register for Channel 0 - High (SAR0_HI)—Offset 4h

Refer to the description for register Source Address Register for Channel 0 - Low.

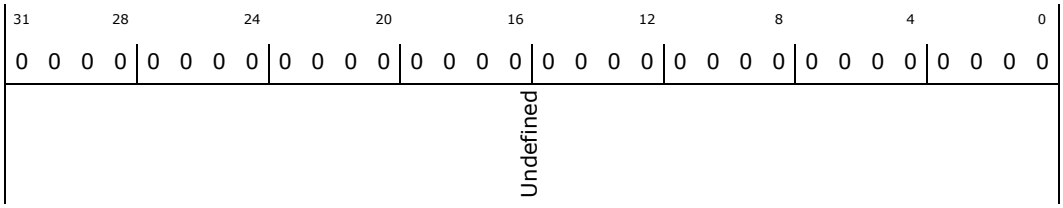
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SAR0_HI: [BAR] + 4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**Undefined:** RESERVED

3.29.3 Destination Address Register for Channel 0 - Low (DAR0_LO)—Offset 8h

The starting destination address is programmed by software before the DMA channel is enabled, or by an LLI update before the start of the DMA transfer. While the DMA transfer is in progress, this register is updated to reflect the destination address of the current AHB transfer.

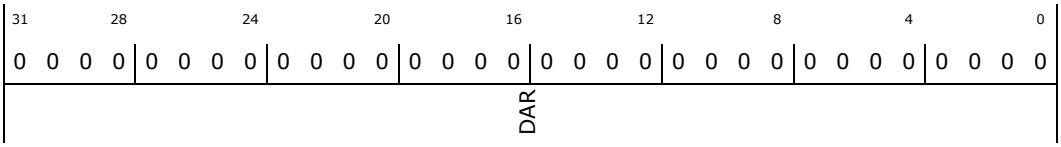
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

DAR0_LO: [BAR] + 8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**Current Destination Address of DMA Transfer (DAR):** Updated after each destination transfer. The DINC field in the CTLx register determines whether the address increments, decrements, or is left unchanged on every destination transfer throughout the block transfer.

3.29.4 Destination Address Register for Channel 0 - High (DAR0_HI)—Offset Ch

Refer to the description for register Destination Address Register for Channel 0 - Low.

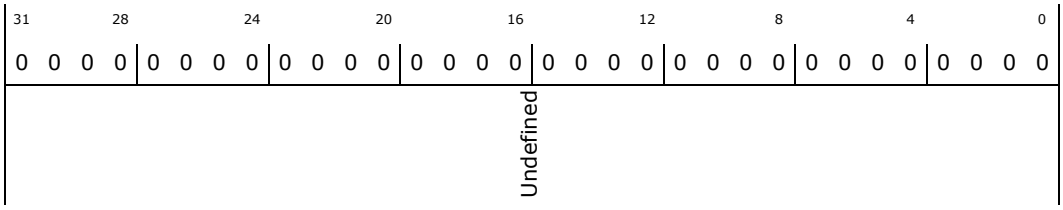
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

DAR0_HI: [BAR] + Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:0	0h RW	**Undefined:** Reserved.

3.29.5 Linked List Pointer Register for Channel 0 - Low (LLP0_LO)—Offset 10h

This register does not exist if the DMAH_CHx_HC_LLP configuration parameter is set to True. For further details, refer to the DesignWare DW_ahb_dmac Databook.

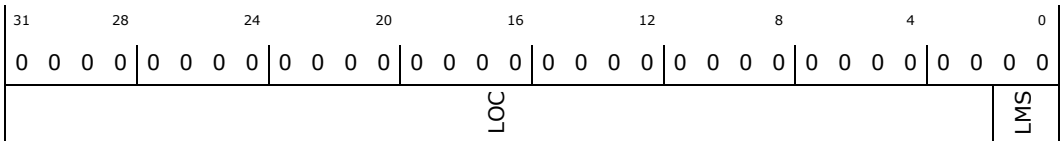
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

LLP0_LO: [BAR] + 10h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:2	0h RW	**LOC:** Starting Address In Memory of next LLI if block chaining is enabled.
1:0	0h RW	**List Master Select (LMS):** Identifies the AHB layer/interface where the memory device that stores the next linked list item resides.

3.29.6 Linked List Pointer Register for Channel 0 - High (LLP0_HI)—Offset 14h

Refer to the description for register Linked List Pointer Register for Channel 0 - Low.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

LLP0_HI: [BAR] + 14h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:0] + 10h

Default: 00000000h

0	1h RW	**Interrupt Enable Bit (INT_EN):** If set, then all interrupt-generating sources are enabled.

3.29.8 Control Register for Channel 0 - High (CTL0_HI)—Offset 1Ch

Refer to the register description for Control Register for Channel 0 - Low.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CTL0_HI: [BAR] + 1Ch

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:0] + 10h

Bit Range	Default & Access	Description
31:13	0h RW	**Undefined_:** RESERVED
12	0h RW	**Done Bit (DONE):** If status write-back is enabled, the upper word of the control register, CTLx[63:32], is written to the control register location of the Linked List Item (LLI) in system memory at the end of the block transfer with the done bit set. Software can poll the LLI CTLx.DONE bit to see when a block transfer is complete. The LLI CTLx.DONE bit should be cleared when the linked lists are set up in memory, prior to enabling the channel. LLI accesses are always 32-bit accesses (Hsize = 2) aligned to 32-bit boundaries and cannot be changed or programmed to anything other than 32-bit. For more information, refer to the DesignWare DW_ahb_dmac Databook.
11:0	2h RW	**Block Transfer Size (BLOCK_TS):** When the DW_ahb_dmac is the flow controller, the user writes this field before the channel is enabled in order to indicate the block size.

3.29.9 Source Status Register for Channel 0 - Low (SSTAT0_LO)—Offset 20h

After each block transfer completes, hardware can retrieve the source status information from the address pointed to by the contents of the SSTATARx register. This status information is then stored in the SSTATx register and written out to the SSTATx register location of the LLI before the start of the next block. Refer to the DesignWare DW_ahb_dmac Databook for further details.

3.29.17 Configuration Register for Channel 0 - Low (CFG0_LO)—Offset 40h

This register contains fields that configure the DMA transfer. The channel configuration register remains fixed for all blocks of a multi-block transfer.

Note: You need to program this register prior to enabling the channel.

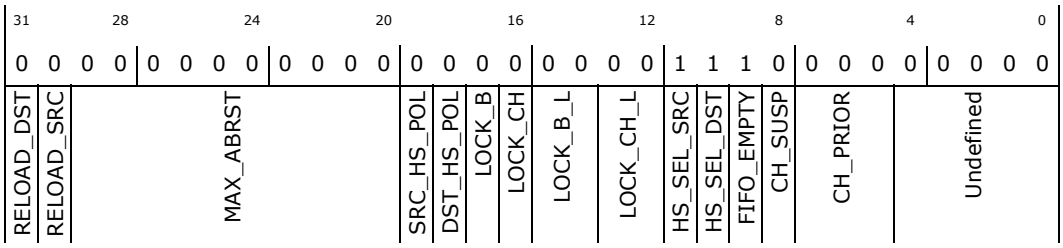
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CFG0_LO: [BAR] + 40h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:0] + 10h

Default: 00000E00h



Bit Range	Default & Access	Description
31	0h RW	**Automatic Destination Reload (RELOAD_DST):** The DARx register can be automatically reloaded from its initial value at the end of every block for multi-block transfers.
30	0h RW	**Automatic Source Reload (RELOAD_SRC):** The SARx register can be automatically reloaded from its initial value at the end of every block for multi-block transfers.
29:20	0h RW	**Maximum AMBA Burst Length (MAX_ABRST):** Maximum AMBA burst length that is used for DMA transfers on this channel. A value of 0 indicates that software is not limiting the maximum AMBA burst length for DMA transfers on this channel.
19	0h RW	**Source Handshaking Interface Polarity (SRC_HS_POL):** • 0 = Active high • 1 = Active low
18	0h RW	**Destination Handshaking Interface Polarity (DST_HS_POL):** • 0 = Active high • 1 = Active low
17	0h RW	**Bus Lock Bit (LOCK_B):** When active, the AHB bus master signal hlock is asserted for the duration specified in CFGx.LOCK_B_L.
16	0h RW	**Channel Lock Bit (LOCK_CH):** When the channel is granted control of the master bus interface and if the CFGx.LOCK_CH bit is asserted, then no other channels are granted control of the master bus interface for the duration specified in CFGx.LOCK_CH_L. Indicates to the master bus interface arbiter that this channel wants exclusive access to the master bus interface for the duration specified in CFGx.LOCK_CH_L.

Bit Range	Default & Access	Description
15:14	0h RW	**Bus Lock Level (LOCK_B_L):** Indicates the duration over which CFGx.LOCK_B bit applies. • 00 = Over complete DMA transfer • 01 = Over complete DMA block transfer • 1x = Over complete DMA transaction
13:12	0h RW	**Channel Lock Level (LOCK_CH_L):** Indicates the duration over which CFGx.LOCK_CH bit applies. • 00 = DMA transfer • 01 = DMA block transfer • 1x = DMA transaction
11	1h RW	**Source Software or Hardware Handshaking Select (HS_SEL_SRC):** • 0 = HW handshaking • 1 = SW handshaking
10	1h RW	**Destination Software or Hardware Handshaking Select (HS_SEL_DST):** • 0 = HW handshaking • 1 = SW handshaking
9	1h RO	**FIFO_EMPTY:** Indicates whether there is data left in the channel FIFO.
8	0h RW	**Channel Suspend (CH_SUSP):** Suspends all DMA transfers from source until this bit is cleared.
7:5	0h RW	**Channel Priority (CH_PRIOR):** Priority of 7 is the highest priority.

31:15	0h RW	**Undefined:** Reserved.
14:11	0h RW	**DEST_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the destination of channel x if the CFGx.HS_SEL_DST field is 0; otherwise, this field is ignored.
10:7	0h RW	**SRC_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the source of channel x if the CFGx.HS_SEL_SRC field is 0; otherwise, this field is ignored.
6	0h RW	**Source Status Update Enable (SS_UPD_EN):** Source status information is fetched only from the location pointed to by the SSTATARx register, stored in the SSTATx register and written out to the SSTATx location of the LLI (refer to Figure 52 on page 243) if SS_UPD_EN is high.
5	0h RW	**Destination Status Update Enable (DS_UPD_EN):** Destination status information is fetched only from the location pointed to by the DSTATARx register, stored in the DSTATx register and written out to the DSTATx location of the LLI if DS_UPD_EN is high.
4:2	1h RW	**PROTCTL:** Protection Control bits used to drive the AHB HPROT[3:1] bus.
1	0h RW	**FIFO Mode Select (FIFO_MODE):** Determines how much space or data needs to be available in the FIFO before a burst transaction request is serviced. • 0 = Space/data available for single AHB transfer of the specified transfer width. • 1 = Data available is greater than or equal to half the FIFO depth for destination transfers and space available is greater than half the fifo depth for source transfers.
0	0h RW	**Flow Control Mode (FCMODE):** Determines when source transaction requests are serviced when the Destination Peripheral is the flow controller. • 0 = Source transaction requests are serviced when they occur. Data pre-fetching is enabled. • 1 = Source transaction requests are not serviced until a destination transaction request occurs.

3.29.19 Source Gather Register for Channel 0 - Low (SGR0_LO)—Offset 48h

The CTLx.SINC field controls whether the address increments or decrements. When the CTLx.SINC field indicates a fixed-address control, then the address remains constant throughout the transfer and the SGRx register is ignored. This register does not exist if the configuration parameter DMAH_CHx_SRC_GAT_EN is set to False. For more information, refer to the DesignWare DW_ahb_dmac Databook.

3.29.105 Configuration Register for Channel 4 - Low (CFG4_LO)—Offset 1A0h

Refer to the register description for Configuration Register for Channel 0 - Low.

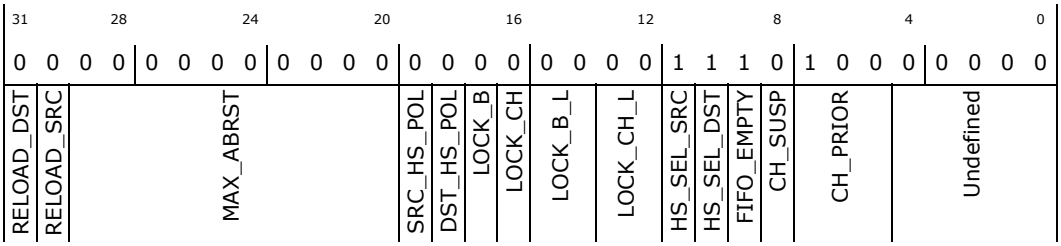
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CFG4_LO: [BAR] + 1A0h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:0] + 10h

Default: 00000E80h



Bit Range	Default & Access	Description
31	0h RW	**Automatic Destination Reload (RELOAD_DST):** The DARx register can be automatically reloaded from its initial value at the end of every block for multi-block transfers.
30	0h RW	**Automatic Source Reload (RELOAD_SRC):** The SARx register can be automatically reloaded from its initial value at the end of every block for multi-block transfers.
29:20	0h RW	**Maximum AMBA Burst Length (MAX_ABRST):** Maximum AMBA burst length that is used for DMA transfers on this channel. A value of 0 indicates that software is not limiting the maximum AMBA burst length for DMA transfers on this channel.
19	0h RW	**Source Handshaking Interface Polarity (SRC_HS_POL):** • 0 = Active high • 1 = Active low
18	0h RW	**Destination Handshaking Interface Polarity (DST_HS_POL):** • 0 = Active high • 1 = Active low
17	0h RW	**Bus Lock Bit (LOCK_B):** When active, the AHB bus master signal hlock is asserted for the duration specified in CFGx.LOCK_B_L.
16	0h RW	**Channel Lock Bit (LOCK_CH):** When the channel is granted control of the master bus interface and if the CFGx.LOCK_CH bit is asserted, then no other channels are granted control of the master bus interface for the duration specified in CFGx.LOCK_CH_L. Indicates to the master bus interface arbiter that this channel wants exclusive access to the master bus interface for the duration specified in CFGx.LOCK_CH_L.

Bit Range	Default & Access	Description
15:14	0h RW	**Bus Lock Level (LOCK_B_L):** Indicates the duration over which CFGx.LOCK_B bit applies. • 00 = Over complete DMA transfer • 01 = Over complete DMA block transfer • 1x = Over complete DMA transaction
13:12	0h RW	**Channel Lock Level (LOCK_CH_L):** Indicates the duration over which CFGx.LOCK_CH bit applies. • 00 = DMA transfer • 01 = DMA block transfer • 1x = DMA transaction
11	1h RW	**Source Software or Hardware Handshaking Select (HS_SEL_SRC):** • 0 = HW handshaking • 1 = SW handshaking
10	1h RW	**Destination Software or Hardware Handshaking Select (HS_SEL_DST):** • 0 = HW handshaking • 1 = SW handshaking
9	1h RO	**FIFO_EMPTY:** Indicates if there is data left in the channel FIFO.
8	0h RW	**Channel Suspend (CH_SUSP):** Suspends all DMA transfers from source until this bit is cleared.
7:5	4h RW	**Channel Priority (CH_PRIOR):** Priority of 7 is the highest priority.
4:0	0h RW	**Undefined:** RESERVED

3.29.106 Configuration Register for Channel 4 - High (CFG4_HI)—Offset 1A4h

Refer to the register description for Configuration Register for Channel 0 - Low.

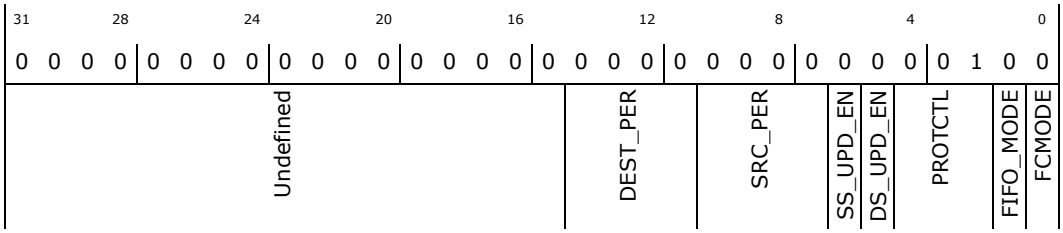
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

CFG4_HI: [BAR] + 1A4h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:0] + 10h

Default: 00000004h



Bit Range	Default & Access	Description
31:15	0h RW	**Undefined:** Reserved.
14:11	0h RW	**DEST_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the destination of channel x if the CFGx.HS_SEL_DST field is 0; otherwise, this field is ignored.
10:7	0h RW	**SRC_PER:** Assigns a hardware handshaking interface (0 - DMAH_NUM_HS_INT-1) to the source of channel x if the CFGx.HS_SEL_SRC field is 0; otherwise, this field is ignored.
6	0h RW	**Source Status Update Enable (SS_UPD_EN):** Source status information is fetched only from the location pointed to by the SSTATARx register, stored in the SSTATx register and written out to the SSTATx location of the LLI (refer to Figure 52 on page 243) if SS_UPD_EN is high.
5	0h RW	**Destination Status Update Enable (DS_UPD_EN):** Destination status information is fetched only from the location pointed to by the DSTATARx register, stored in the DSTATx register and written out to the DSTATx location of the LLI if DS_UPD_EN is high.
4:2	1h RW	**PROTCTL:** Protection Control bits used to drive the AHB HPROT[3:1] bus.
1	0h RW	**FIFO Mode Select (FIFO_MODE):** Determines how much space or data needs to be available in the FIFO before a burst transaction request is serviced. • 0 = Space/data available for single AHB transfer of the specified transfer width. • 1 = Data available is greater than or equal to half the FIFO depth for destination transfers and space available is greater than half the fifo depth for source transfers.
0	0h RW	**Flow Control Mode (FCMODE):** Determines when source transaction requests are serviced when the Destination Peripheral is the flow controller. • 0 = Source transaction requests are serviced when they occur. Data pre-fetching is enabled. • 1 = Source transaction requests are not serviced until a destination transaction request occurs.

3.29.107 Source Gather Register for Channel 4 - Low (SGR4_LO)—Offset 1A8h

Refer to the register description for Source Gather Register for Channel 0 - Low.

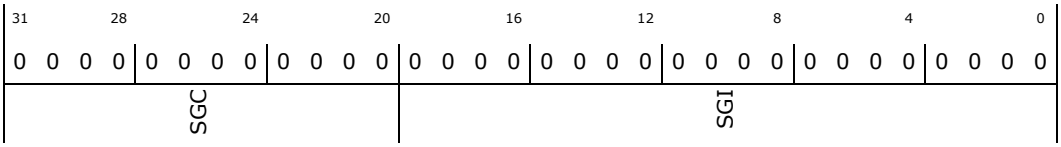
Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SGR4_LO: [BAR] + 1A8h

BAR Type: PCI Configuration Register (Size: 32 bits)
BAR Reference: [B:0, D:24, F:0] + 10h

Default: 00000000h



Bit Range	Default & Access	Description
31:20	0h RW	**Source Gather Count (SGC):** Source contiguous transfer count between successive gather boundaries. Refer to the DesignWare DW_ahb_dmac Databook for further details.
19:0	0h RW	**Source Gather Interval (SGI):** Refer to the description for SGR0_LO.SGI.

3.29.108 Source Gather Register for Channel 4 - High (SGR4_HI)—Offset 1ACh

Refer to the register description for Source Gather Register for Channel 0 - Low.

Access Method

Type: Memory Mapped I/O Register (Size: 32 bits)

SGR4_HI: [BAR] + 1ACh
